When bronchogenic carcinoma arises in the peripheral portion of the lung, it may grow without involving a major bronchus. For this reason the usual symptoms of cough and hemoptysis may not appear for many months. A malignant lesion of this type is seen on the roentgenogram as a single circumscribed mass. The size of the mass depends on the age and rapidity of growth of the lesion. The smaller the nodule is when first encountered the more likely it is to be considered benign by both roentgenologist and consulting physician. The prognosis following re-

From the Section on Roentgenology, Mayo Clinic, Rochester, Minnesota.

Read at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 7, 1948.

moval of such a lesion is usually very favorable, yet, a course of watchful waiting is frequently advised instead of operation.

Seventy-four per cent of fifty-three single scribed mass in the lung is malignant far outweighs the risk of exploration. Add to this the fact that most of the benign lesions encountered in this type of case are best treated by surgical

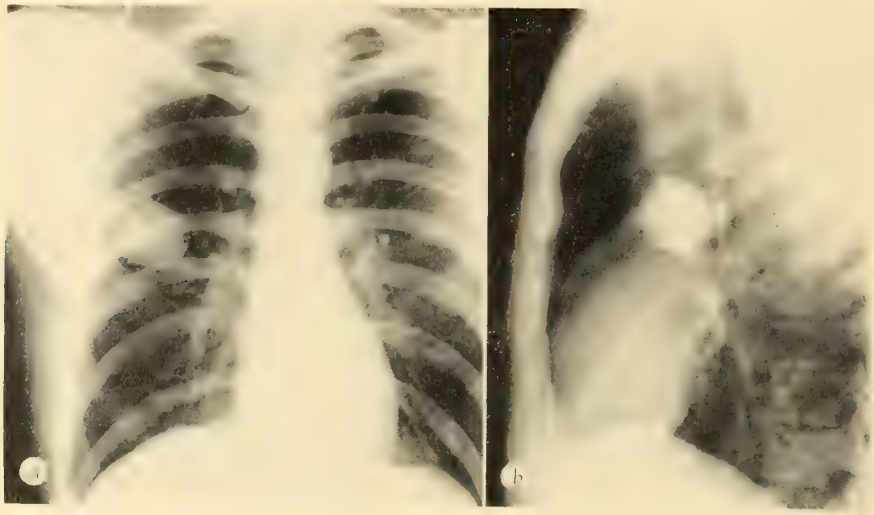

Fig. 1 (Case 1). Round mass in right upper lobe which proved to be hamartoma; *a*, anteroposterior; *b*, lateral view.

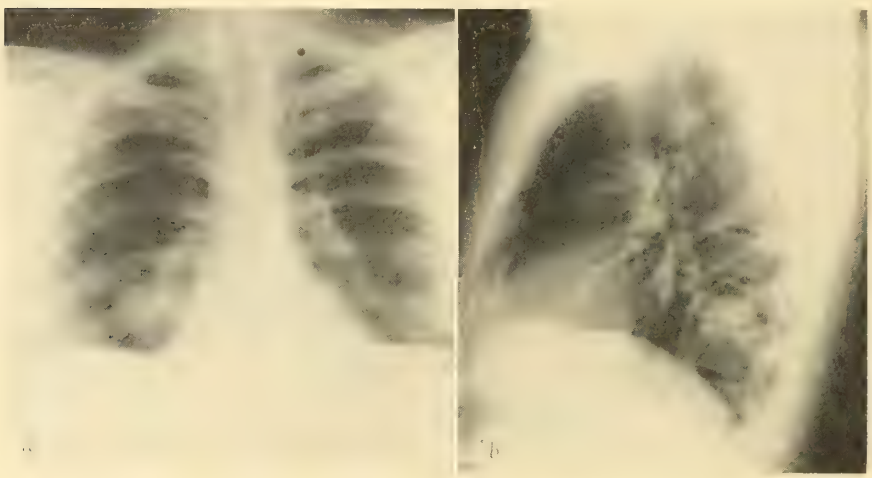

Fig. 2 (Case 2). Round mass in right lower lobe which proved to be a carcinoma; *a*, anteroposterior; *b*, lateral view.

nodular pulmonary lesions proved to be malignant when exploratory operation was performed by Clagett after all other means of diagnosis had been exhausted.[2] On the other hand, the risk of exploratory thoracotomy is less than 1 per cent in the hands of competent thoracic surgeons. Certainly, if the tumor has eluded diagnosis by all other means, the chance that a single circumextirpation and the arguments in favor of immediate exploration far outweigh those in favor of watchful waiting.

Case 1.—A man, thirty-four years old, was rejected by the Army in 1944 because of a shadow seen in the roentgenogram of the lungs made at the time of his examination for induction. The roentgenologic examination was repeated at intervals subsequently and in

December, 1945, he was told that the shadow had grown larger (Fig. 1 *a* and *b*). Although he had no symptoms referable to the respiratory system he was operated on. The right upper lobe was removed and a benign hamartoma was found.

Case 2.—A man, thirty-four years old, was rejected by the Army in 1944 because of a shadow seen on the roentgenogram of the lungs made at the time of his examination for induction. The roentgenologic examination was repeated at intervals subsequently and sometime in 1945 he was told that the shadow had grown larger (Fig. 2 *a* and *b*). He had recently experienced pain in the chest and had expectorated some blood-streaked sputum. He was operated on and right lower lobectomy was performed. In the right lower lobe of the lung was found an adenocarcinoma of the bronchogenic variety.

Cases 1 and 2 illustrate the difficulty experienced by the roentgenologist in distinguishing a carcinoma from a benign tumor. Both men were the same age. Both tumors were discovered at the time of examination for induction into the Army and both showed evidence of growth on subsequent roentgenograms. The only point of difference was the fact that the patient who harbored the carcinoma had symptoms referable to the respiratory system while the other patient had none.

Carcinoma Simulating a Pulmonary Abscess

Sometimes a carcinoma in the peripheral portion of the lung undergoes necrosis or an abscess cavity forms in the lung behind a malignant lesion which obstructs a bronchus. In either instance the roentgenologic picture may imitate that of pulmonary abscess. In such a case the malignant nature of the lesion may be overlooked while conservative measures are employed in treatment. Valuable time is lost in waiting for the cure which will not follow.

It is difficult to formulate a hard and fast rule of procedure for cases of this sort. Conservative measures have a place in the treatment of pulmonary abscess, although there is a growing tendency on the part of thoracic surgeons to consider an open type of operation or lobectomy as the treatment of choice. The fact that carcinoma of the lung may masquerade as a pulmonary abscess must always be kept in mind. Graham and associates stated that "about 10 per cent of the cases of chronic lung abscess in the adult have been associated with a carcinoma of the lung or bronchus." In a series of 165 cases of pulmonary carcinoma reported by Overholt 8 per cent were thought to be cases of pulmonary abscess when first seen. Certainly all physicians should maintain a high degree of suspicion for all chronic cavitating lesions of the lung encountered in adult patients. All possible diagnostic procedures should be employed in an endeavor to uncover the exact nature of the lesion. Study of the bronchial secretions, bronchoscopy with biopsy and even exploratory thoracotomy are to be recommended.

Too much emphasis should not be placed on the thickness of the wall of the abscess, the presence or absence of surrounding pneumonitis or other roentgenologic features, for it has been found that none of these are truly indicative of the benignancy or malignancy of the lesion. Neither should negative findings from analysis of the sputum or from bronchoscopic examination be taken to indicate a benign process.

Case 3.—A man, fifty-three years old, was first seen at the Mayo Clinic in 1944 because of asthma. A roentgenogram of the chest at that time showed no evidence of disease. He returned three years later because he had suffered from hemoptysis, pain in the chest and loss of weight. A lesion had been found in the right lung by means of the roentgenologic examination (Fig. 3 *a* and *b*). Examination of the sputum disclosed no malignant cells. Pus was seen in the bronchus of the right upper lobe at the time of bronchoscopy, but no tumor was noted. The patient was operated on and a chronic pulmonary abscess was found in the right upper lobe of the lung. Open drainage was established.

Case 4.—A man, fifty-one years old, had suffered from asthma for ten years. For three months he had experienced pain in the chest and had expectorated bloody sputum. Roentgenograms of the chest showed a lesion in the right lower lobe (Fig. 4 *a* and *b*). Bronchoscopic examination was done and tissue removed from the bronchus to the right lower lobe was said by the pathologist to show squamous cell epithelioma. Surgical exploration was performed, but the lesion proved to be inoperable.

Cases 3 and 4 illustrate the frequent impossibility of distinguishing roentgenologically between a cavitating carcinoma and a lung abscess. Both patients had suffered from asthma for several years. Both had experienced recent attacks of pain and hemoptysis. Because the lesion was accessible to the bronchoscopist in the case of the carcinoma a diagnosis was possible before sur-

gical exploration. If it had been situated in a part of the lung in which it could not be reached bronchoscopically, surgical intervention would have been necessary to establish the diagnosis, are administered, the patient may respond rapidly, sometimes even may appear cured subjectively. The proper diagnosis in such cases will be overlooked if the physician fails to order a

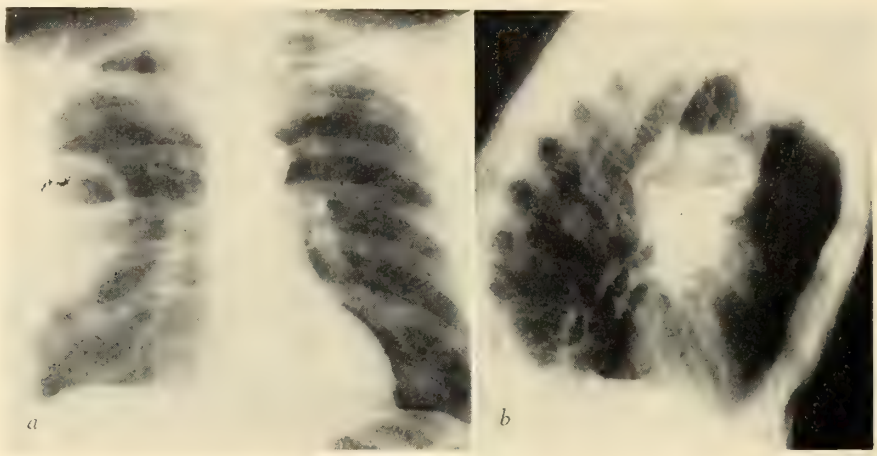

Fig. 3 (Case 3). Cavitating lesion with fluid level which proved to be a chronic pulmonary abscess; *a*, anteroposterior; *b*, lateral view.

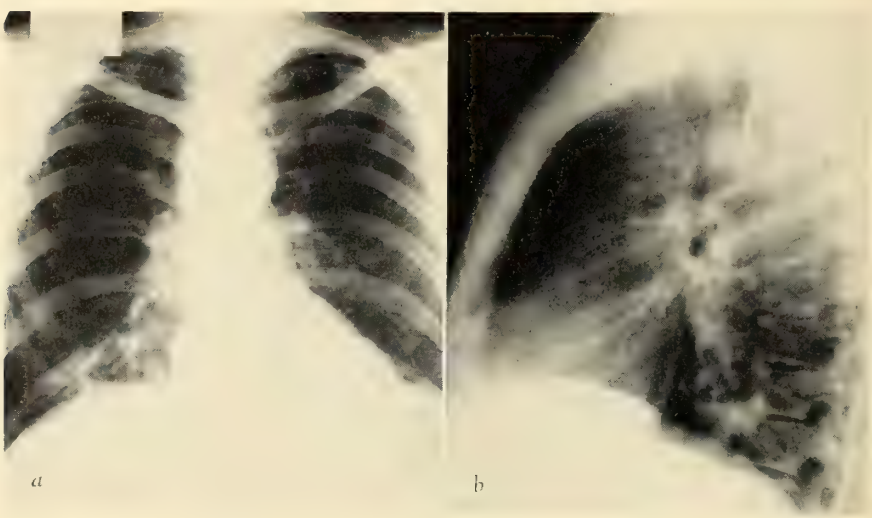

Fig. 4 (Case 4). Cavitating lesion with fluid level which proved to be a carcinoma; *a*, anteroposterior; *b*, lateral view.

just as it was in the case of the pulmonary abscess.

Carcinoma Simulating Pneumonia

Many pulmonary carcinomas develop in the major bronchi and cause bronchial obstruction. Often it happens that the onset of symptoms coincides with the development of this obstruction. In these cases the history, physical findings and roentgenologic features may mimic those of pneumonia. If penicillin or other antibiotic agents follow-up roentgenogram. Not until the next attack of bronchial obstruction occurs or until other signs appear which necessitate revaluation of the diagnosis will the exact nature of the disease be suspected.

If carcinoma is the underlying cause of the patient's illness, the roentgenologic appearance of the lungs will not return to normal, no matter how good the response to therapy. In order to be on the safe side no adult patient who has suffered from an attack of what appears to be

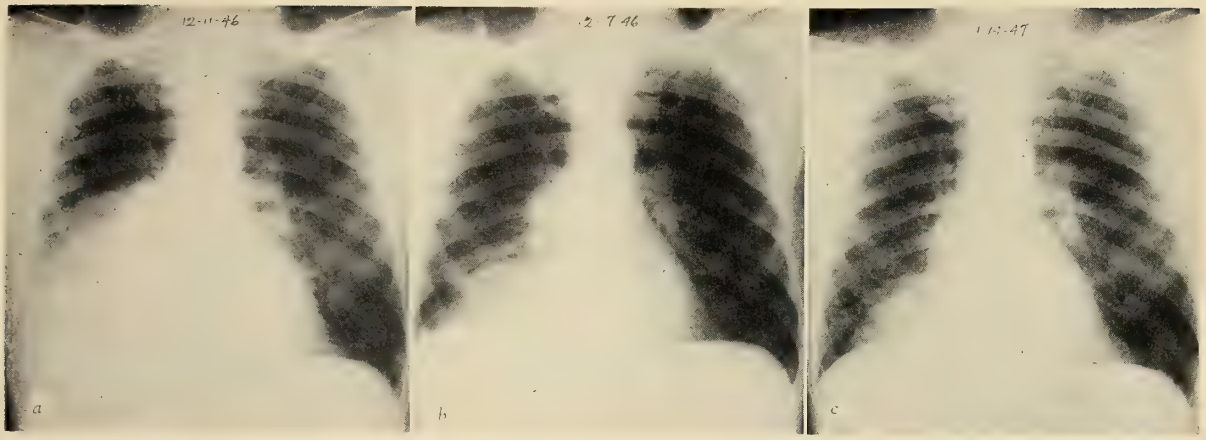

Fig. 5 (Case 5). *a*, Lesion of right lower lobe which was thought to be pneumonia; *b*, same lesion a week later after patient had received penicillin. The lesion appears to be less extensive, as though it were improving; *c*, five weeks after *a* the lesion is still present. It proved to be a carcinoma at the junction of the bronchi to the right middle and lower lobes.

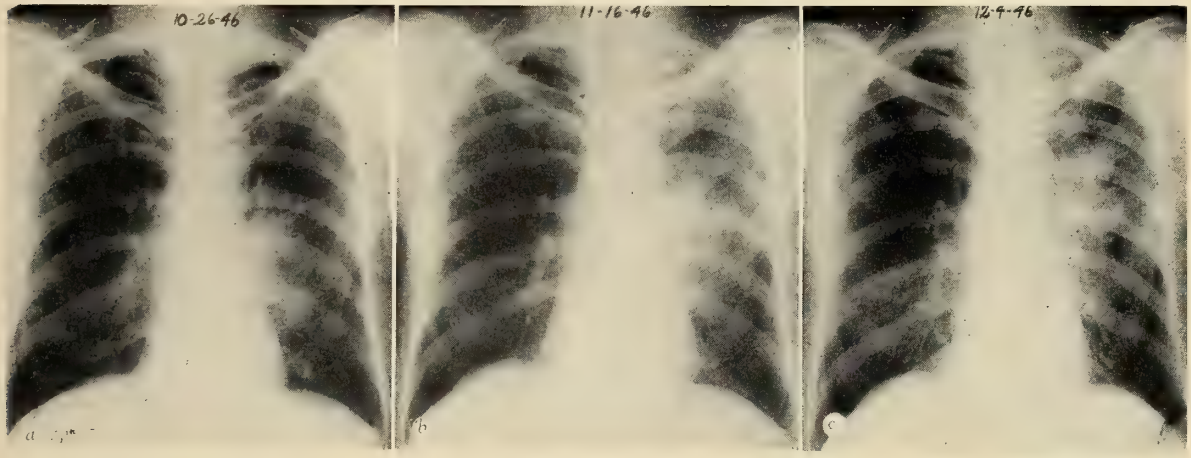

Fig. 6 (Case 6). *a*, Lesion in left lung which was thought to be pneumonia; *b*, same lesion three weeks later after patient had received penicillin. The lesion is not only still present but is more extensive; *c*, same lesion five and one half weeks after *a*. It proved to be a carcinoma of the bronchus to the left upper lobe.

pneumonia should be considered to be well until a follow-up roentgenogram of the chest shows complete disappearance of the lesion originally noted. As long as a shadow persists in the lung all of the usual methods of examination, such as study of the bronchial secretions, bronchoscopy, bronchography, and even exploratory thoracotomy should be employed to uncover the true nature of the disease.

Case 5.—A man, sixty-four years old, became acutely ill and experienced chills and high fever. He entered a hospital where a diagnosis of pneumonia was made after roentgenologic examination (Fig. 5 *a*). Treatment with penicillin, streptomycin and one of the sulfonamides was begun. He improved rapidly. Within a few days his temperature had returned to normal and another roentgenogram was made which showed a decrease in the involvement of the lungs (Fig. 5 *b*).

A week or so following his dismissal from the hospital fever recurred. A roentgenogram made about four weeks after his last examination showed that the lesion in the right lung had not disappeared (Fig. 5 *c*). For this reason a bronchoscopic examination was carried out. A carcinoma was found at the junction of the bronchi to the right middle and lower lobes.

Case 6.—A man, sixty-nine years old, was first examined in September, 1945. He was found to have benign hypertrophy of the prostate. A roentgenogram of the chest made at that time was considered to be normal. The patient returned in October, 1946, with symptoms referable to the urinary tract. He was found to have a temperature of 100.4° F. He said that he had caught cold three days before, had suffered from a chill and had begun to cough at that time. Roentgenologic examination revealed a lesion in the left lung which was thought to represent pneumonia (Fig. 6 *a*). The patient entered a hospital and was treated with penicillin for ten days. When at the end of this period

his fever did not subside and a roentgenogram showed the lesion in the left lung to persist, bronchoscopy was performed. No tumor was seen, nor did the bronchial secretions contain malignant cells.

The patient was kept under observation. Roentgenograms were made at intervals and these continued to show the lesion in the left lung (Fig. 6 *b* and *c*). Another bronchoscopic examination failed to find malignant cells or tissue. Finally, exploratory thoracotomy was advised. At operation a squamous cell epithelioma was found involving the bronchus to the left upper lobe. Pneumonectomy was carried out.

Cases 5 and 6 illustrate the type of carcinoma of the lung which imitates pneumonia from the clinical and roentgenologic points of view. Both patients were thought to have pneumonia and both were treated with antibacterial agents. In each case the true nature of the disease was discovered because subsequent roentgenograms failed to show complete disappearance of the lesion. Even when clinical signs and symptoms of pneumonia disappear, follow-up roentgenograms should be made to be sure that the disease is no longer present. A persistent shadow on the roentgenogram demands further investigation.

Summary and Conclusions

Three of the pitfalls which delay the early diagnosis of carcinoma of the lung result from the tendency for this malignant lesion to masquerade in benign costume. The pitfall of the benign tumor can be avoided by the early use of exploratory thoracotomy whenever a single circumscribed mass which eludes diagnosis by all other methods is present in the lung. The pitfall of the pulmonary abscess can be avoided by the analysis of sputum, bronchoscopy, and biopsy and even exploratory thoracotomy in all cases of chronic cavitating disease of the lung encountered in an adult patient for which some specific etiologic factor cannot be found. The pitfall of pneumonia can be avoided by the use of the follow-up roentgenogram, and by maintenance of a high degree of suspicion for any lesion which does not disappear roetgenologically in ten to fourteen days. A constant awareness of these problems by all physicians will make for earlier diagnosis of malignant disease of the lung. This in turn will improve the results of surgical procedures, the only satisfactory method of treatment for this disease known today.

THE FORTIFICATION OF MILK WITH VITAMINS A AND D

For many years the Council on Foods and Nutrition has approved fortification of milk with vitamin D. The Council has stated the opinion that fortification of milk as a general purpose food with vitamin A is not in the interest of public health. However, no objection is taken to the concurrent presence of vitamin A when the preparation used for fortifying with vitamin D contains vitamin A in natural association.

The Food and Drug Administration, in defining a standard of identity for evaporated milk, took no exception to the concurrent presence of both vitamins A and D in fortifying agents when both vitamins are derived from natural sources.

Fish liver oil concentrates, sometimes used for fortifying milk with vitamin D, often contain relatively large amounts of vitamin A. Milk fortified with such concentrates has been accepted by the Council, and a statement of vitamin A content has been permitted on the label. However, claims concerning increased nutritive value because of the vitamin A content have not been permitted.

Before the Council can accept claims for milk fortified with vitamin A it seems desirable to have evidence that such fortification is in the interest of public health, even though the procedure is apparently harmless. Such evidence appears to be lacking. Diets that contain appropriate amounts of milk are likely to contain adequate vitamin A. The evidence now available does not warrant a change in the standing decisions of the Council on Foods and Nutrition concerning specific fortification of specific foods to include fortification of milk with vitamin A.

In its acceptance of milk fortified with preparations from natural sources that contain both vitamins A and D, the Council has assumed that the presence of vitamin A is incidental. In those instances in which the vitamin A component is adjusted to supply a specified amount, presumably the amount of vitamin A is not incidental and fortuitous. In any case, the addition of vitamin A does not constitute sufficient reason for acceptance of advertising that suggests special nutritional advantages. The addition of vitamin A to milk, already a good source of this nutrient, may add to the cost of the milk and is without apparent advantage to public health.—Council on Foods and Nutrition, J.A.M.A., 138:23, (Sept. 4) 1948.

The A. H. Sanford Lectureship

Introduction to Lectureship

KANO IKEDA, M.D.

Saint Paul, Minnesota

The members of the Minnesota Society of Clinical Pathologists are highly honored to have the privilege of sponsoring an annual Lectureship in Pathology and dedicating it to the Minnesota State Medical Association, in honor of one of its own members, Dr. Arthur H. Sanford, Rochester, Minnesota.

The objective of the lectureship is twofold: first, to honor one of its most distinguished members who stands among the few foremost clinical pathologists of the day, and who has contributed heavily towards the moulding of the present-day science of medical diagnosis through laboratory methods; and secondly, through its medium, to bring the clinical pathologist closer to everyday practice of medicine, whereby the place of clinical pathology and laboratory diagnosis may be made more fully appreciated by the general practitioner.

It is hoped by the members of the Minnesota Society of Clinical Pathologists that these lectures to be delivered at a general session of the Minnesota State Medical Association, annually, by an outstanding man in the specialty which they represent, may be the means of perpetuating these objectives.

Dr. Arthur H. Sanford, a native of the state of Iowa, received his Master's degree in physiology, followed by a degree of Doctor of Medicine, from Northwestern University in 1907. He served as professor of physiology at Marquette University until 1911, when he came to the Mayo Clinic as bacteriologist. He became director of clinical laboratories and head of the section of clinical pathology, and since April, 1946, has been senior consultant in the section of clinical pathology. He is professor of clinical pathology of the Mayo Foundation, and special consultant of the United States Public Health Service. He received a Northwestern University alumnus award in 1940. Dr. Sanford is a founding member and past president of the American Society of Clinical Pathologists and of the American Board of Pathology, and a member of numerous scientific organizations and honor societies. He is a co-inventor with Dr. Charles Sheard, of the Mayo Clinic, of one of the first electro-photometric instruments to be put into practical use in the clinical laboratory, and the originator of numerous useful laboratory procedures which are employed daily in diagnosis. He is the author of many scientific articles dealing with clinical pathology. Dr. Sanford is well known for his popular textbook, "Clinical Diagnosis by Laboratory Methods," which is universally recognized as one of the most authoritative books on clinical pathology and laboratory medicine.

The members of the Minnesota Society of Clinical Pathologists are fortunate indeed to have, as a fellow member, a man of Dr. Sanford's attainments, whose leadership in their specialty is recognized wherever scientific laboratory methods are employed in medical diagnosis. We honor ourselves by dedicating to you this annual lectureship to honor Dr. Sanford, a pioneer clinical pathologist, for his contributions to the practice of medicine, which may be a perpetual source of inspiration to the practicing physicians of Minnesota.

* * *

A brief remark by Dr. Sanford followed.

The first A. H. Sanford Lecture was delivered by Dr. Robert Hebbel for Dr. E. T. Bell, Professor of Pathology and Head of the Department, The University of Minnesota Medical School, on "Pathology of Diabetes." This lecture is being published elsewhere.

Introduction of the 1948 Speaker

A. S. BAGGENSTOSS, M.D.

President of the Minnesota Society of Clinical Pathologists

Members of the Minnesota State Medical Association and Guests: At the inauguration of the Arthur H. Sanford Lectureship last year, the distinguished secretary and former president of our Society, Dr. Kaño Ikeda, stated that the objective of this lectureship is twofold: first, to honor one of its most distinguished members, Dr. Sanford, who stands among the foremost clinical pathologists of the day; and, second, to bring the clinical pathologist closer to the everyday practice of medicine to the end that the place of clinical pathology and laboratory diagnosis may be more fully appreciated by the general practitioner.

In the furtherance of these objectives, we have been fortunate indeed in obtaining as our speaker for the occasion, Dr. Benjamin J. Clawson, Professor of Pathology at the University of Minnesota. Dr. Clawson received his Doctor of Medicine degree in 1917 and his Doctor of Philosophy degree in 1919 at the University of Chicago. The trite expression, "he needs no introduction" was never more apt, for he has been on the faculty of the University of Minnesota since 1921. For many of you, as for me, this occasion will awaken memories of a kindly, stimulating and forceful teacher. Those of you who have had the fortunate experience of being a student under him know whereof I speak. However, it is not only as a teacher but as an investigator that Dr. Clawson has left his mark. No one in the medical world of today can write or talk or even think of heart disease or rheumatic fever without mentioning his name. Of his many outstanding contributions, I shall take time to mention only a few: his studies on the etiology of rheumatic fever, the pathogenesis of calcareous aortic stenosis, the Aschoff body, the relationship of subacute bacterial endocarditis to rheumatic endocarditis, the experimental work on the use of B.C.G. as an immunizing agent and his classic chapter on diseases of the heart in Dr. Bell's textbook. As one might anticipate, this scientific productivity has received recognition by his election to numerous scientific and honorary societies and inclusion of his name in several compendiums of outstanding scientists: the American Association of Pathologists and Bacteriologists; the American Society of Bacteriologists; Sigma Xi; and American Men of Science—to mention but a few of them. It is with great pleasure that I present to you Dr. Benjamin J. Clawson, who will speak on Rheumatic and Bacterial Endocarditis.

Dedicatory address at the Minnesota State Medical Association, at Duluth, July 1, 1947.

RHEUMATIC AND BACTERIAL ENDOCARDITIS

1740 Cases

B. J. CLAWSON, M.D.
Minneapolis, Minnesota

THIS discussion is an analysis of the types of endocarditis from a group of 1,740 cases of rheumatic and bacterial endocarditis in 37,725 autopsies (4.6 per cent) and in a total of 6,283 cardiac deaths in the same series of autopsies (27.6 per cent) (Table I). Of the 1,740 cases of endocarditis, 1,104 (63.4 per cent) are rheumatic and 636 (36.6 per cent) are bacterial (Table II). When it is remembered that nearly 90 per cent of the cases of bacterial endocarditis have a background of rheumatic valvulitis, it becomes evident that the rheumatic cases greatly outnumber the bacterial.

TABLE I. INCIDENCE OF RHEUMATIC AND BACTERIAL ENDOCARDITIS
37,725 autopsies and 6,283 cardiac deaths

	Per cent Autopsies	Per cent Cardiac deaths
A. Rheumatic (1,104 cases)	2.9	17.6
B. Bacterial endocarditis (626 cases)	1.7	10.1
C. Total (1,740 cases)	4.6	27.7

Depending upon the stage of the disease at which death occurred, the rheumatic group is divided into acute rheumatic endocarditis, recurrent rheumatic endocarditis, valve deformities and adherent pericardium. The bacterial group is separated into primary and secondary acute bacterial endocarditis, in which the clinical course is not more than six weeks, and subacute bacterial endocarditis, which has a duration of more than six weeks. The incidence of each type is shown in Table II.

It is impossible to study one of the two types of endocarditis without considering the other. This is especially true of the bacterial type, since it so commonly has a background of rheumatic endocarditis, acute, recurrent, or valve deformities (healed or nearly healed). The relationships in many cases are similar, but dissimilar ones are encountered. An effort is made to evaluate the significance of these relationships. The chief relationships observed and analyzed may be grouped as clinical, bacteriological, immunological and anatomical.

TABLE II. INCIDENCE OF TYPES OF RHEUMATIC ENDOCARDITIS (2.9 PER CENT) AND BACTERIAL ENDOCARDITIS (1.7 PER CENT)
37,725 autopsies, a total of 1,740 cases (4.6 per cent)

	Percentage of groups	Percentage of total group
Rheumatic (1,104)	100.0	63.4
1. Acute rheumatic (116)	10.5	6.6
2. Recurrent rheumatic (101)	9.2	5.8
3. Valve deformities (850)	77.0	48.8
4. Adherent pericardium (37)	3.3	2.1
Bacterial (636)	100.0	36.6
1. Primary acute (55)	8.7	3.2
2. Secondary acute (135)	21.2	7.8
3. Subacute (446)	70.1	25.6

Clinical Relationships

Age.—Age is an outstanding clinical dissimilar relationship. Rheumatic endocarditis is the type found primarily in the pediatric wards, while on the other hand, the internist generally sees the subacute bacterial type. The separating line is close to the fifteenth year.

Cohn,[5] in his analysis of a large number of cases of rheumatic endocarditis, found that the first manifestations of acute rheumatic endocarditis occurred under thirteen years of age in 86 per cent of his cases. Gelfman,[7] in an analysis of 578 cases of rheumatic heart disease, found subacute bacterial endocarditis as a cause of death to be particularly low under the age of ten. In an analysis of the ages in which death occurred in ninety-eight cases of acute rheumatic endocarditis and 417 cases of subacute bacterial endocarditis, I found that 83.3 per cent of the individuals with acute rheumatic endocarditis who died in the first attack were under twenty years of age. Only 11 per cent of the 417 cases of subacute bacterial endocarditis were under twenty years of age at

From the Department of Pathology, University of Minnesota Medical School. Presented as the A. H. Sanford Lecture at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 7, 1948.

TABLE III. AGES AT WHICH DEATH OCCURRED

Acute rheumatic endocarditis (96 cases); subacute bacterial endocarditis (417 cases)

Decades	Acute rheumatic		Subacute bacterial	
	No.	Per cent	No.	Per cent
1	40	41.6	8	1.9
2	40	41.6	38	9.1
3	9	9.3	91	21.8
4	5	5.2	98	23.5
5	1	1.0	79	18.9
6	0	0.0	56	13.4
7	0	0.0	36	8.6
8	1	1.0	8	1.9
9	0	0.0	3	0.7
10	0	0.0	0	0.0
Below 20	80	83.3	46	11.0
Above 20	16	16.6	371	88.9

TABLE IV. INTERVAL BETWEEN ACUTE RHEUMATIC ENDOCARDITIS AND THE BEGINNING OF SUBACUTE BACTERIAL ENDOCARDITIS

In patients 20 years old or younger (25 cases)

Interval	No.	Per Cent
1. Continuous	17	68.0
2. Two months to one year	3	12.0
3. Three years	2	8.0
4. Eight years	1	4.0
5. Nine years	1	4.0
6. Twelve years	1	4.0

the time of death (Table III). The reason for this age difference in the two types of endocarditis has not been determined.

Transition of Acute Rheumatic into the Subacute Bacterial.—A gradual passing of acute rheumatic endocarditis into the bacterial type is commonly observed by the clinicians and the pathologists. The bacterial type is more severe clinically and before the use of penicillin nearly always ended fatally. An original diagnosis of acute rheumatic endocarditis is often changed to subacute bacterial endocarditis, if the case progresses toward a fatal termination. In a group of twenty-five cases of established subacute bacterial endocarditis in patients not more than twenty years old, seventeen (68 per cent) had a continuous course from acute rheumatic endocarditis into the typical subacute bacterial type. In three, the periods between the manifestations of the two diseases were two months to one year (Table IV). The transition from the acute rheumatic to the subacute bacterial type may be so gradual that it is impossible to say where the one ends and the other begins.

Background of the Subacute Bacterial Type.—A third clinically observed relationship is that in

TABLE V. EVIDENCES OF A RHEUMATIC BACKGROUND IN SUBACUTE BACTERIAL ENDOCARDITIS

219 cases

Evidence	Number Examined	Number Positive	Per Cent Positive
1. History of rheumatism	101	82	81.2
2. Thickened involved valve	219	151	68.9
3. Thickened noninvolved valve	219	22	10.0
4. One or more	219	178	81.3

TABLE VI. HOW DEATH OCCURS WITH RHEUMATIC HEART DISEASE

1407 cases

Kinds	No.	Per cent
Acute rheumatic	114	8.1
Recurrent rheumatic	97	6.8
Valve deformities	784	55.7
Adherent pericardium	37	2.6
Subacute bacterial endocarditis	375*	26.7
Total	1407	99.9

*90 per cent of subacute bacterial endocarditis.

nearly 90 per cent of the cases of subacute bacterial endocarditis there is a background of a rheumatic valvular lesion, acute, partially healed or completely healed (Christian[2]). Christian observed that the determinative background of subacute bacterial endocarditis was rheumatic heart disease in 89.33 per cent of 150 consecutive adult cases of subacute bacterial endocarditis caused by *streptococcus viridans* and in 90.24 per cent of 174 consecutive adult cases of subacute bacterial endocarditis of all causes studied at the Peter Bent Brigham Hospital. In a series of 219 of our cases of subacute bacterial endocarditis, in which descriptions were sufficient to permit a fairly accurate evaluation of the degree of valvular deformity and in which a history of rheumatism was given, it was apparent that a background of rheumatic fever was present in at least 178 of the 219 cases (81.3 per cent) (Table V).

Subacute Bacterial Endocarditis a Cause of Death in Rheumatic Heart Disease.—A fourth clinical relationship is that subacute bacterial endocarditis is the primary cause of death in from 25 to 30 per cent of all cases of rheumatic valve deformities. Table VI shows how death occurred in 1,407 cases of rheumatic heart disease. On the basis of there being a rheumatic background in 90 per cent of the cases of subacute bacterial endocarditis, it is noted that 26.7 per cent of all patients with rheumatic heart diseases died from subacute bacterial endocarditis. When the acute

and recurrent rheumatic cases are omitted, the percentage is increased to about 30.

TABLE VIII. MAXIMUM STREPTOCOCCIC AGGLUTINATION TITERS IN NORMAL PEOPLE, ACUTE RHEUMATIC ENDOCARDITIS AND SUBACUTE BACTERIAL ENDOCARDITIS

Dilution	Below 50	50	100	200	400	800	1600	3200	6400	12800	Above 400
Normal (81)	2%	5%	2%	18.5%	44.7%	26%	2%	0%	0%	0%	28%
Acute rheumatic (81)	0%	1%	0%	1%	9.%	15%	10%	26%	28%	10%	92%
Subacute bacterial (13)	0%	0%	0%	0%	7.6%	7.6%	7.6%	0%	46.2%	30.8%	89%

Bacterial Relationships

The organisms found in the blood stream in both types are usually *Streptococcus viridans,* a few per cubic centimeter of blood in the acute rheumatic when present and many in the bacterial. While the general belief is that acute rheumatic fever is in some way closely related to hemolytic streptococcic sore throat, yet, as stated by Jones[4] and according to the observations of others, the organisms found in the blood stream are generally *Streptococcus viridans.* There are different opinions concerning the significance of these organisms in the blood. Streptococci have been cultured in from 50 to 60 per cent of patients with acute rheumatic fever. In a series of 252 of our cases of subacute bacterial endocarditis, there were positive bacterial findings reported in 207 (82.1 per cent). Of these, *Streptococcus viridans* was the organism cultured from the blood in 170 (67.5 per cent) (Table VII).

TABLE VII. BACTERIAL FINDINGS IN SUBACUTE BACTERIAL ENDOCARDITIS

252 cases

Organisms	Number	Per Cent
1. Str. viridans	170	67.5
2. Str. hemolyticus	16	6.3
3. Staphylococcus	14	5.5
4. Brucella	4	1.6
5. H. influenzae	1	0.4
6. Gonococcus	2	0.8
Total	207	82.1

Immunological Relationships

Humoral Antibodies.—Both types of endocarditis have high titers of streptococcic humoral antibodies, as agglutinins, precipitins, complement-fixing antibodies and, generally in the acute rheumatic type, antistreptolysins. These antistreptolysins tend to disappear, since they are present in only about 30 per cent of individuals with healed valve deformities in whom obviously previous attacks of acute rheumatic endocarditis have occurred (Wimblad[12]). The maximum streptococcic agglutination titers in normal individuals and in those with acute rheumatic endocarditis and subacute bacterial endocarditis are recorded in Table VIII. The percentage of positive findings in dilutions above 1-400 is approximately the same in the two types of endocarditis and definitely higher than in the normal cases.

Hypersensitiveness.—Skin tests to streptococci or streptococcic products are positive in 75 to 85 per cent of patients with acute rheumatic endocarditis, 50 per cent in those with healed valve deformities, and are generally negative in those with subacute bacterial endocarditis (Birkhaug,[1] Gibson, Thomson and Stewart,[8] and Favour, Janeway and Gibson and Levine[6]).

The bacterial type of allergy in rheumatic fever has been studied by Swift,[10] Birkhaug,[1] Thomson, Gibson and Stewart,[8] and others. It has been shown by intradermal skin tests that a high percentage of patients with acute rheumatic fever are allergic to streptococci and that patients with bacterial endocarditis who have been clinically cured by penicillin therapy again become hypersensitive.[6] This suggests that patients having bacterial endocarditis had previously been allergic but had been desensitized by heavy blood stream infection.

A point to be considered in thinking of the role of delayed hypersensitiveness in rheumatic endocarditis is whether the rheumatic child was allergic before contracting rheumatic fever or whether

allergy exists as a result of rheumatic infection or of intercurrent infections with increasing age. Birkhaug's[1] observations showed that 20 per cent of normal children and 85 per cent of rheumatic children were allergic to streptococci. Gibson, Thomson and Stewart,[8] by skin tests with extracts of hemolytic streptococci, found that the percentage of allergy rose from the age of five years to that of fifteen years, when it ceased to increase in both rheumatic and control children. At fifteen years of age, there was practically no difference in the frequency and the degree of allergy to *Streptococcus hemolyticus* extracts (68 per cent in rheumatic, 66 per cent in controls). They concluded that their word did not add much to support the allergy theory in the pathogenesis of acute rheumatic fever. The same conclusion was reached by Jones.[9] Clawson and Wetherby[3] found that 50 per cent of apparently normal people gave a positive intracutaneous reaction to *Streptococcus viridans*. Hypersensitiveness to streptococcic products is rare in young children when acute rheumatic fever begins, but is common in adults. It is especially high in both children and adults who have or have recently had rheumatic fever. Rheumatic fever seldom occurs for the first time in adults, and bacterial endocarditis is rare in adults except in people who have previously had rheumatic endocarditis. It may be suspected that allergy may be a factor in the beginning of bacterial endocarditis, rather than in the rheumatic type.

Anatomical Relationships

Gross Vegetations.—In the endocarditis immediately associated with acute rheumatic fever (rheumatic endocarditis, simple verrucous endocarditis), the heart valves on gross examination show small, rather smooth, globular nodules at points of contact of the leaflets a short distance back from the free margin on the atrial surfaces of the mitral and tricuspid and on the ventricular surfaces of the aortic and pulmonary valves. Usually these vegetations are not extensive enough to interfere seriously with the function of the valves.

In subacute bacterial endocarditis, the vegetations are, in the main, large, soft and villous. The consistency and size of the subacute bacterial vegetations make it easily possible for particles to break loose into the blood stream and produce the embolic processes so commonly found in subacute bacterial endocarditis.

Microscopic Vegetations.—Microscopically, the acute rheumatic lesions show the inflammation within and throughout the substance of the leaflet. The elevated nodules form only at the line of contact of the leaflets. An important histological feature is the presence of hyaline fibrinoid material within the valves. A small platelet thrombus is present in which bacteria are not found. A cellular inflammatory reaction occurs with the fibrinoid changes and is chiefly a proliferative inflammation. The cells are spindle-shaped and rounded, generally with an abundant cytoplasm. They are usually mononuclear, but multinucleated forms are common. They are derived from fibrocytes, histiocytes, blood lymphocytes and from a special histiocyte, the Anitschkow cell. This cell is peculiar in being found only in the heart. Definite Aschoff nodules are frequently seen in the acutely inflamed valve.

In subacute bacterial endocarditis all the structures of the acute rheumatic valve are present, and in addition there is large platelet thrombus in which many bacteria, generally in colonies, are usually found. The infected thrombus is the distinguishing characteristic lesion of bacterial endocarditis.

Vegetations characteristic of the rheumatic type may generally be found on the same cusps with the vegetations of the subacute bacterial type (80 per cent Clawson,[4] 100 per cent Von Glahn and Pappenheimer[11]). Acute rheumatic vegetations may be present on the cusp of one valve, while on another there may be subacute bacterial lesions. Recent observations have illustrated how the presence of the two types of lesions can be demonstrated on the same valve. Typical cases of subacute bacterial endocarditis cured by penicillin therapy have come to autopsy with death from other causes. The large villous vegetations were absent, and organisms could not be cultured from the blood or found in the valve by the Gram-Weigert stain. Within the valve, the inflammatory reaction was typically that of acute or recurrent rheumatic endocarditis.

Valves Involved.—The valvular involvement in acute rheumatic endocarditis and bacterial endocarditis is noted in Table IX. In either group,

the aortic and mitral are the only valves involved to any extent. The tricuspid alone and the pulmonary alone are seldom involved in the acute rheumatic type but are more frequently affected in the subacute bacterial.

brain 42 (11.5 per cent), kidneys and brain 7 (1.9 per cent) or a total of 256 (70.3 per cent). Embolic phenomena are not present with acute rheumatic endocarditis. Evidence of embolic processes is a dissimilar relationship.

TABLE IX. VALVE INVOLVEMENT IN ACUTE RHEUMATIC AND SUBACUTE BACTERIAL ENDOCARDITIS

	Valves														
Kinds	A	M	T	P	AM	AT	AP	AMT	AMP	AMTP	MT	MP	MTP	TP	Total
Acute Rheumatic	2	43	0	1	24	0	0	10	0	9	9	0	0	0	98
Subacute Bacterial	65	137	7	7	132	4	1	6	1	0	3	0	0	0	363
Total	67	180	7	8	156	4	1	16	1	9	12	0	0	0	461

TABLE X. COMBINATIONS OF VALVULAR INVOLVEMENT

Aortic alone, mitral alone, and aortic and mitral combined, per thousand autopsies in rheumatic heart disease and bacterial endocarditis

	Males					Females				
	No.	A	M	AM	Total	No.	A	M	AM	Total
Rheumatic	478	8.1	8.1	9.9	26.2	300	2.2	18.7	9.8	30.8
Subacute bacterial	217	3.0	3.8	5.0	11.9	111	1.4	6.0	3.9	11.4

TABLE XI. MYOCARDITIS IN ACUTE RHEUMATIC AND SUBACUTE BACTERIAL ENDOCARDITIS

	Aschoff nodules		Diffuse inflammation		Abscesses		Peri-arterial scars		One or more	
	No.	%	No.	%	No.	%	No.	%	No.	%
Acute rheumatic (295)	47	67.2	12	17.9	2	2.9	21	31.3	53	79.1
Subacute bacterial (60)	27	45.0	36	60.0	13	21.5	38	63.5	53	88.5

The relation of sex to the three kinds of valvular involvement (aortic alone, mitral alone and mitral and aortic combined) is of interest in showing a low aortic involvement and a high mitral involvement in the females (Table X). This is most pronounced in the rheumatic group, but it is definitely significant also in the subacute bacterial group. This anatomical relationship shows a marked similarity in the two groups.

Embolic Phenomena.—Evidences of embolic phenomena are common with subacute bacterial endocarditis. In 364 cases embolic phenomena were present as follows: spleen 72 (19.7 per cent), kidneys 22 (6 per cent), brain 14 (3.8 per cent), spleen and kidneys 88 (24.1 per cent), spleen and brain 11 (3.0 per cent), spleen, kidneys and

The Myocardium.—The various types of inflammation are seen in Table XI. The Aschoff nodule is less frequent in subacute bacterial endocarditis, 45 per cent, while in the acute rheumatic endocarditis it was present in 67.2 per cent of the cases. Von Glahn and Pappenheimer found the Aschoff nodule to be present in 46 per cent of the cases of subacute bacterial endocarditis which they studied. Abscesses are more common in the subacute bacterial type. Evidences of inflammation, acute or healed, occurred in 79.1 per cent of the acute rheumatic cases and in 88.5 per cent of the subacute bacterial cases.

Pericarditis.—The presence or absence of pericarditis has at times been used to differentiate acute rheumatic endocarditis from subacute bac-

terial endocarditis. Table XII shows the frequency of pericarditis in our cases of acute and recurrent rheumatic endocarditis, in healed rheumatic valvular deformities and in subacute bacterial endocarditis. Pericarditis is more frequent in the acute type of rheumatic endocarditis (41.5 per cent). This incidence does not represent the clinical incidence for the acute pericarditis evidently contributes largely as cause of death.

TABLE XII. FREQUENCY OF PERICARDITIS IN RHEUMATIC ENDOCARDITIS AND SUBACUTE BACTERIAL ENDOCARDITIS

	Number with pericarditis	Per cent
Acute and recurrent rheumatic endocarditis (183)	86	41.5
Healed valve deformities (671)	125	18.5
Total rheumatic (854)	211	24.7
Subacute bacterial endocarditis (364)	78	21.4

The frequency of pericarditis with the entire group of rheumatic hearts closely represents the clinical incidence of pericarditis with acute rheumatic endocarditis. It is obvious that in the cases of rheumatic valvular deformities there has been an acute rheumatic endocarditis. Evidently, in the cases of healed valve deformity in which there is no acute pericarditis or adherent pericardium, there never has been an acute pericarditis; for the type of pericarditis (fibrinous) which is associated with acute rheumatic fever undergoes organization early in its course, and permanent fibrous adhesions result. The incidence of pericarditis with the group of rheumatic hearts is 24.7 per cent, only slightly higher than the incidence with subacute bacterial endocarditis (21.4 per cent). Since the incidence of pericardial involvement in the total number of rheumatic heart disease cases represents closely the actual clinical incidence of pericarditis with acute rheumatic endocarditis, and since this incidence is nearly the same as the incidence of pericarditis in cases of subacute bacterial endocarditis, it appears obvious that the presence or absence of pericarditis cannot be used clinically to differentiate the two types.

Interpretations of the Relationships of Acute Rheumatic and Subacute Bacterial Endocarditis

The relationships are mostly similar with the following exceptions in the subacute bacterial type: the older age at which the endocarditis appears, the more severe clinical course, the greater ease with which organisms are recovered from the blood stream, the general absence of streptococcic allergy, the larger and infected thrombus on the valve and the embolic phenomena.

The first of these dissimilar relationships may possibly be explained by a difference of streptococcic hypersensitiveness in the two age groups. The remaining four differences may be accounted for by the effect of the large infected thrombus, the characteristic valvular lesion in subacute bacterial endocarditis.

From a study of the various relationships of the two types of endocarditis, two different theories have evolved:

1. The two types of endocarditis are different diseases.
   (a) A healed rheumatic valve becomes infected.
   (b) An acute rheumatic vegetation becomes infected with another infective agent.
2. They are the same disease etiologically, with different clinical and pathological manifestations.

Which or whether either of these two theories is correct has not yet been answered.

Summary

1. Rheumatic heart disease causes about 3 per cent of all deaths and 17.5 per cent of the cardiac deaths. Bacterial endocarditis causes about 1.5 per cent of all deaths and 10 per cent of cardiac deaths.

2. Approximately 90 per cent of the cases of subacute bacterial endocarditis have a rheumatic background.

3. From 25 to 30 per cent of patients with rheumatic heart disease finally die with subacute bacterial endocarditis.

4. Close clinical, bacteriological, immunological and anatomical relationships exist between rheumatic endocarditis and bacterial endocarditis.

5. The significance of these relationships has not been definitely determined in all cases.

6. It cannot be conclusively determined from human cases of endocarditis whether acute rheumatic endocarditis and subacute bacterial endo-

(Continued on Page 1105)

VAGOTOMY FOR PEPTIC ULCER: A FOLLOW-UP STUDY OF TWENTY CASES

ROBERT C. LAM, M.D.
Minneapolis, Minnesota

THE object of the present paper is not to attempt to settle the current controversial and often inconsistent points of view on vagotomy for the treatment of peptic ulcer, but rather to present some data based on the study of the first twenty patients thus treated at the Asbury Hospital during the past two years. Because of the small number of cases and the short lapse of time, the data, as well as the few conclusions derived from them, are by no means decisive and final, and can only serve to provoke further argument on the efficacy of vagotomy for the treatment of peptic ulcer, an argument which, in all likelihood, will continue for many years to come. It has been said that discoveries in medicine are perennially made, discarded, forgotten, and then rediscovered, and their significance and values are finally established. This might very well be the case with vagotomy.

TABLE I. DISTRIBUTION OF AGE AT ONSET AND ON ADMISSION IN TWENTY PATIENTS

8		1
Average	31.2 yrs.	48.9 yrs.

The present series comprises twenty cases of vagotomy performed at the Asbury Hospital between February, 1946, and November, 1947. In this series there are seventeen males and three females, a ratio of about six to one. The distribution of age at onset of symptoms and on admission, and the duration of the peptic ulcer and of medical treatment are respectively illustrated in Tables I and II.

Nine of the twenty patients had a history of bleeding, and three of them of perforation, of whom two had a surgical closure. Of the series of twenty, seventeen had duodenal ulcer, one had gastric ulcer, and two had both. The operations

Dr. Lam is a Resident in Surgery, Asbury Hospital, Minneapolis.

DU—Duodenal Ulcer
GU—Gastric Ulcer
TV—Transthoracic Vagotomy
AV—Abdominal Vagotomy
GE—Gastroenterostomy
GR—Gastric Resection

were performed by six different surgeons designated as A, B, C, D, E and F, and lesions and operations are shown in Table III. Fifteen patients with duodenal ulcer including one having had a gastroenterostomy twenty-eight years previously and a revision of the gastroenterostomy twelve years ago, were treated by transthoracic vagotomy. One patient with duodenal ulcer was treated by abdominal vagotomy and another by abdominal vagotomy with gastroenterostomy. One patient with both duodenal and gastric ulcer was treated by abdominal vagotomy and gastroenterostomy, and another patient with both duodenal and gastric ulcer was treated by transthoracic vagotomy with a subsequent gastric resection and gastroenterostomy.

In the follow-up study, the patients were interviewed, x-rayed and asked to answer a question-

naire, four to twenty-five months postoperatively. They were also asked to give their own opinions on the results of vagotomy for the treatment of their peptic ulcers. On the basis of the x-ray appearance of the stomach and duodenum preoperatively and postoperatively, the relief of symptoms, the presence of complications and the general well-being of the patient as a whole, the result in each case was then evaluated as will be illustrated later on.

X-Ray Studies

X-ray studies were made of the entire group of patients, ranging from two to twenty-four months subsequent to operation. Evidence of active duodenal ulcer, which was found on x-ray in seventeen patients before operation, was absent in all seventeen after vagotomy. The result from the x-ray viewpoint is therefore 100 per cent satisfactory. Deformity of the duodenal cap was as constant a feature after as before the operation, whereas irritability and spasm of the cap was present in five patients before but in none after vagotomy.

In the stomach, hypertrophic gastritis, which was encountered in eight patients preoperatively, disappeared after operation. A lesion at the pylorus, in the form of spasm, irregularity, deformity, adhesion or obstruction, was present in the three patients with gastric ulcer, and disappeared with the gastric ulcer after vagotomy and gastroenterostomy in two patients, but persisted with the gastric ulcer after simple vagotomy in the third. Another patient with a partially obstructed pylorus without ulcer showed deformity after simple vagotomy.

In the group with simple vagotomy, there is a tendency towards initial retention of secretion and food, delayed emptying, decreased tone, dilatation and reduced peristalsis postoperatively as compared with the gastric motility preoperatively. A decrease in gastric motility was apparent in five patients before, and was evident in thirteen patients after, simple vagotomy. In the group with vagotomy and gastroenterostomy, no such appreciable change was noted.

In five patients where more than one x-ray was made following simple vagotomy, there was a gradual improvement or return of the gastric motility, and in one patient the gastric motility which had been decreased before the operation resumed normally postoperatively.

TABLE IV. COMPARISON OF 12-HOUR GASTRIC NIGHT SECRETION

A.O.: 16 cases			P.O.: 6 cases			Follow-up: 3 cases		
Amount	Free Hcl	Total Hcl	Amount	Free Hcl	Total Hcl	Amount	Free Hcl	Total Hcl
670 c.c.	71	104	487 c.c.	12	39	497 c.c.	36	93

Figures represent average values in each group.

Gastric Acidity

The twelve-hour night secretion test for gastric acidity was not routinely carried out in all patients, and the technique of the test was not uniform. It was made in sixteen patients preoperatively and repeated in six patients immediately after simple vagotomy. A follow-up study was carried out in three patients from three to ten months postoperatively. The average figures of total secretion, free HCl and total HCl are indicated in Table IV. It is noted that hyperacidity which is present preoperatively tends to diminish postoperatively. This may be more than coincidental with the x-ray findings in which the gastric motility was decreased in those cases where a decreased acidity was present postoperatively.

The insulin test for gastric acidity, believed to be invaluable in ascertaining the completeness of the section of the vagus nerve, was done in only one patient in this series and is not included in the study. The results from the twelve-hour night secretion test performed in patients of the present series are a relative measure of acidity and are to be interpreted as such accordingly.

Relief of Symptoms

Although incomplete relief of symptoms in some patients and persistence of symptoms in a few were encountered, the relief of symptoms was, in general, definite. Seven patients had complete relief of their preoperative symptoms, whereas thirteen had incomplete relief or persistence of one or more of their original complaints. However, if the intensity, the frequency and the duration of these symptoms are considered, a marked improvement following operation was noted. The pain now is not as constant a feature as it used to be, and it does not affect the patients' daily activities nor interrupt their sleep. Gas, when present, can be easily eructed. In fact, except in two patients who are psychoneurotic, all these symptoms of pain, gas and belching, nausea

and vomiting, fullness and distress, when still present after vagotomy, are well under control so long as the patients do not indulge in dietary indiscretion.

Body Weight

The body weight of the twenty patients is compared before and after survey. The body weight at the time of follow-up, ranging from four to twenty-five months postoperatively, when compared with the minimal weight previous to surgery indicates that three show no change and seventeen show a gain of from 5 to 70 pounds. The average gain thus compared is 17.4 pounds. When compared with the usual weight previous to operation, four show no change, six show a loss of from 5 to 25 pounds, and ten show a gain of from 5 to 20 pounds. The average gain thus compared is 2.8 pounds. It is noted that patients who were overweight from the effects of the ulcer diets were able to reduce to normal weight and that underweight patients were able to eat normally and gain weight after vagotomy.

Diet

According to the tolerance of various foods, the patients are divided into four groups. Those who could tolerate only a strict diet before the operation but can enjoy a liberal diet after operation belong to Group I. There are five patients in this group. Those who could tolerate a limited diet before, but can enjoy a liberal diet after surgery are classified as Group II. There are three patients in this group. In Group III are four patients who could only tolerate a strict diet before but can enjoy a moderate diet after surgery. In Group IV are seven patients who could tolerate a limited diet before but can tolerate a moderate diet after operation. In one patient no change is observed after operation.

Tobacco could not be tolerated before, but is tolerated well or in moderation after operation in four patients. The same is observed in the case of alcohol. Two patients show no improvement in the tolerance of tobacco and alcohol postoperatively.

Activities

In seventeen of the twenty patients the daily activities were interrupted with a variable amount of work loss attributed to the ulcer before operation. Postoperatively, fourteen have been able to resume their normal activities without any loss of work, and three were still doing light work at the time of the follow-up. Of the remaining three patients, one was feeling weak and tired and thought that age was against him. One was as anemic and listless as before, and was later found to have a cancer of the uterus. One who never let his ulcer interfere with his work, but had to spend from $600 ao $1,200 a year for medical care for five years previous to operation, has been working in a fuller capacity since the operation.

Psychic Factor

Fourteen of the patients indicate that they are nervous and high-strung individuals with excessive stress and strain and undue worries and excitements. Their own expressions are "discontented childhood," "dissatisfied home life," "things made me sick," "disappointed in love," et cetera. Seven patients of this group showed improvement after operation, and described their improvement as "full of pep," "with ambition never had before," "feel like a new person," "life's worth living," "never worry about things that can't be helped." Two psychoneurotic patients, both with an intestinal disorder, were skeptical about the results of vagotomy. One of them is now much improved after some psychotherapy, but the other, who has been informed of the inadvisability of vagotomy by one doctor and advised to have a gastroenterostomy by another, still has a number of indefinite complaints. One patient who does not belong to this group stated that while on a strict milk diet during a bad attack of ulcer, the news of his father's death brought about a severe attack of pain and bleeding so that he was confined to bed for two weeks. Another patient who also does not belong to this group recalled that the onset of his illness was preceded by a fight with a business associate. The incident occurred at a time after his wife had just had an operation. One patient belonging to the group of fourteen found no relief of his nervous condition after twelve months and doubted whether vagotomy is beneficial in nervous conditions.

Surgical Morbidity and Complications

There is no mortality in this series, and the results in general are satisfactory. Regardless of the type of operation performed, the postoperative stay in the hospital was about ten days on the

TABLE V. GASTRO-VISCERAL AND OTHER COMPLICATIONS IN TWENTY PATIENTS

TV—Transthoracic Vagotomy
AV—Abdominal Vagotomy
GE—Gastroenterostomy

average. The patients were usually allowed up on the third day and were allowed a diet on the fourth postoperative day.

Pulmonary complications, in the form of pleurisy, pneumothorax, emphysema, atelectasis and pleural thickening, only occurred following simple vagotomy and were present clinically in ten patients. In the x-ray follow-up of the series, pleural thickening was found in fourteen patients. By comparing the results observed clinically and those from x-ray follow-up, it is noted that some of these complications were detected clinically only, some in the x-ray only, and some both clinically and in the x-ray, totally in sixteen patients.

In Table V the gastrovisceral and other complications are listed. Diarrhea, which probably develops from an imbalance between the sympathetic and parasympathetic nervous systems, appeared in seven patients, and was relieved in five after a period of two to three months postoperatively, but had persisted off and on in two patients up to eleven months and fourteen months, respectively, when last interviewed. One of the latter two patients is a psychoneurotic previously mentioned. Abdominal pain developed in three patients, two of whom are the psychoneurotics. Incisional pain was encountered in three patients, the severest up to three months postoperatively. Belching was found in four patients, but was considered by all except one as a relief of the gas which they used to have. There were, in addition, three cases of numbness, two cases of fullness and one case of distress. The gastrovisceral and other complications, in one or more forms, therefore developed in fourteen (70 per cent) of the patients, including the two with psychoneurosis. It is noted, however, that all these complications are generally not severe enough to cause much discomfort. They are transitory and have a tendency to disappear in the course of time.

Résumé of Illustrative Cases

Case 1.—DW 48F. Gas pain, vomiting, fullness for forty years. Duodenal ulcer diagnosed for twenty-two years. Medical treatment for two years. X-ray: Active duodenal ulcer, cap deformity. Transthoracic vagotomy on 2-23-46. X-ray, one month: Stomach with moderate retention. Cap deformity without active duodenal ulcer. Twenty-three months: Stomach with minimal retention, 40 per cent emptying at four hours, moderate dilatation, shallow peristalsis. Cap deformity without active duodenal ulcer. Pleural thickening. Follow-up, twenty-five months: Some gas, fullness occasionally. Incisional pain one to two months. Feeling well in general.

Case 2.—IB 43M. Gas pain, constipation for seven years. Duodenal ulcer diagnosed for two years. Medical treatment for two years. History of bleeding. Psychoneurosis. Irritable colon. Prejudiced against medical treatment. X-ray: Active duodenal ulcer, cap deformity. Hypertrophic gastritis, eccentrically placed pylorus. Transthoracic vagotomy on 5-18-46. X-ray, twenty-two months: Stomach with retention, 100 per cent emptying at four hours, slight dilatation. Cap deformity without active duodenal ulcer. Pleural thickening. Follow-up, twenty-two months: Some gas pain, belching, pain in right lower quadrant, persistent constipation. Feeling better after psychotherapy.

Case 3.—AB 61M. Gas pain, distress for thirty-two years. Duodenal ulcer diagnosed for twenty-eight years. Medical treatment for ten years. Gastroenterostomy twenty-eight years ago. Revision of gastroenterostomy twelve years ago. Bleeding in 1935. X-ray: Active duodenal ulcer, cap deformity, irritability, spasm. Nonfunctioning gastroenterostomy. Transthoracic vagotomy on 6-21-47. X-ray, four months: Stomach with 70 per cent emptying at four hours. Cap deformity without active duodenal ulcer: Nine months: Stomach with slight retention; 85 per cent emptying at four hours; tone good. Cap deformity without active duodenal ulcer. Follow-up, nine months: Some gas pain, distress, belching, diarrhea occasionally. Constipation.

Case 4.—RL 42M. Gas pains for eleven years. Duodenal ulcer diagnosed for two years. Medical treatment for one year. History of bleeding. X-ray: Active duodenal ulcer. Hypertrophic gastritis. Abdominal vagotomy on 11-7-47. X-ray, two months: Stomach with retention, 10 per cent emptying at four hours, atonic, slightly dilated, peristalsis weak. Cap deformity without active duodenal ulcer. Pleural thickening. Follow-up, four months: Some gas pain, belching, diarrhea. Feeling well in general.

Case 5.—BT 51M. Pain for thirty years. Duodenal ulcer diagnosed for one year. Medical treatment for one year. X-ray: Active duodenal ulcer, cap deformity.

DU—Duodenal Ulcer
GU—Gastric Ulcer
SC—Surgical Closure
GR—Gastric Resection

TV—Transthoracic Vagotomy
GE—Gastroenterostomy
AV—Abdominal Vagotomy

Abdominal vagotomy with gastroenterostomy on 5-17-47. X-ray, ten months: Stomach with normal emptying at four hours, no dilatation. Cap deformity without active duodenal ulcer. Follow-up, ten months: Some belching, fullness.

Case 6.—JK 54M. Pain, nausea for fourteen years. Duodenal and gastric ulcer diagnosed for four years. Medical treatment for two years. X-ray: Active duodenal ulcer, cap deformity. Prepyloric ulcer, pyloric spasm. Transthoracic vagotomy on 2-20-47. X-ray, four months: Stomach with retention, 1 per cent emptying at four hours, atonic, pylorus with complete mechanical obstruction. Eleven months: Stomach with retention, 40 per cent emptying at four hours, tone good, peristalsis very shallow. Twelve months: Stomach with 50 per cent emptying at six hours, peristalsis shallow, pylorus irregular, gastric ulcer. Cap deformity without active duodenal ulcer. Pleural thickening. Follow-up, twelve months: Some pain, persistent nausea, vomiting, diarrhea, fullness, distress. Gastric resection on 2-11-48. Prepyloric ulcer found perforated. Feeling well since.

Case 7.—AS 71M. Pain, distress for nineteen years. Gastric ulcer diagnosed for eight years. Medical treatment for one year. Perforation in 1945 with surgical closure. X-ray: Gastric ulcer on lesser curvature, hypertrophic gastritis, pyloric spasm, marked retention with 10 per cent emptying at four hours. Cap deformity without active duodenal ulcer. Abdominal vagotomy with gastroenterostomy on 4-2-47. X-ray, ten months: Stomach with 90-95 per cent emptying at four hours, slight dilatation. Gastroenterostomy functioning well. Follow-up, ten months: Feeling well.

Summary and Conclusions

The entire series consists of twenty patients studied from four to twenty-five months postoperatively. On the basis of x-ray evidence of healing of the ulcer and gastric motility, the relief of symptoms, the development of gastrovisceral complications and the general well-being of the patient as a whole, the result in each patient is estimated as excellent, good, fair or poor. The x-ray findings of the stomach and duodenum were found, on the whole, to correspond closely to the patient's state of health, and these objective findings are therefore taken as more reliable criteria in the evaluation of the results. On the other hand, the psychic factor in peptic ulcer plays just as important a role as in other diseases. How the patient himself feels before and after operation therefore deserves due consideration.

In fifteen patients with duodenal ulcer preceding transthoracic vagotomy, the results were excellent in six, good in seven and fair in two. One of these patients with a previous gastroenterostomy and a revision of the gastroenterostomy, which was nonfunctioning at the time of his admission for vagotomy, has a good result after

the operation. In two patients with psychoneurosis the result was good in one and fair in the other. One patient with duodenal ulcer was treated by abdominal vagotomy and another by abdominal vagotomy with gastroenterostomy. The results were good in both instances.

Abdominal vagotomy together with gastroenterostomy was performed on two patients, one with gastric ulcer and the other with both gastric and duodenal ulcer. The results in both cases were excellent, but the indication for vagotomy is questionable. Transthoracic vagotomy was performed on another patient with both gastric and duodenal ulcer. The result was poor. A prepyloric ulcer which had perforated was found during a subsequent gastric resection.

From the study of this series, it is evident that vagotomy is indicated in duodenal ulcer, and the results are favorable. On the whole, the surgical morbidity is low. The ulcer heals readily, and no subsequent operation is usually necessary. The relief of symptoms is definite. A more liberal diet is tolerated and the resumption of normal daily activities follows.

The incidence of pulmonary and gastrovisceral complications is high. But, as far as could be determined, they seem to be of no serious import and tend to disappear in the course of time.

Vagotomy is contraindicated in gastric ulcer because of the possibility of malignancy and perforation.

Acknowledgment

The author wishes to acknowledge his appreciation to Mr. W. Dayton Shields, administrator of the Asbury Hospital, for financing this study; to Dr. Robert E. Nord, roentgenologist at the Asbury Hospital, for reading and checking the x-rays; to Dr. Thomas A. Peppard for his encouragement and suggestions; and to Dr. Roscoe C. Webb for his inspiration, criticism and guidance.

RHEUMATIC AND BACTERIAL ENDOCARDITIS

(Continued from Page 1099)

carditis are two separate diseases occurring together in approximately 90 per cent of the cases of subacute bacterial endocarditis, or whether they are different manifestations of one disease.

CLINICAL-PATHOLOGICAL CONFERENCE

DIAGNOSTIC CASE STUDY
With Literature Review

HAROLD H. JOFFE, M.D., and ARTHUR H. WELLS, M.D.

Duluth, Minnesota

DR. A. H. WELLS: We wish to present a difficult diagnostic problem for your careful consideration. Then, Dr. Joffe will briefly review four additional cases of the disease found in our hospital records and summarize the literature on the subject.

DR. C. H. MEAD: (Case No. 43235) This woman, a business school instructor, was admitted to the hospital at the age of twenty-two on December 15, 1936, because of right lower quadrant pain of two years' duration, with loss of appetite, diarrhea and 5-pound weight loss during the previous two months. In addition, she complained of daily frontal headaches, occasional scotomata and frequent upper respiratory infections. Physical examination at that time was essentially negative. Urinalyses showed nothing unusual. Hemoglobin determination, red blood cell count, white blood cell count and differential count were not done. A preoperative diagnosis of recurrent appendicitis was made and on December 16, 1936, an exploratory laparotomy was performed, at which time a cholecystectomy and appendectomy was done. Pathologic studies revealed cholelithiasis, chronic cholecystitis and a normal appendix.

The patient was again admitted on June 4, 1948, with a history of crampy right lower quadrant pain, malaise, and diarrhea which had persisted since her operation in 1936. The foregoing symptoms had been gradually becoming more severe with four to five bowel movements daily and a weight loss of approximately 6 pounds since January of 1948. Only on one occasion, Christmas of 1947, did she notice some blood in the stools. In addition, she complained of occasional difficulty in swallowing, dizzy spells, and some backache. The patient appeared to be emotionally immature, living with two sisters and one brother, all older than herself and all unmarried.

Physical examination revealed a slight fever of 99.2 degrees, with mild but diffuse tenderness on deep palpation of the right lower quadrant. Urinalyses were essentially negative. The hemoglobin was 11.5 grams, with a red blood cell count of 4,060,000. The white blood cell count was 14,700 with 76 per cent neutrophiles. The sedimentation rate (Westergren) was 77 mm. per hour. The Kline test was negative. A chest plate revealed nothing unusual. An intravenous pyelogram revealed a reduplication of the left kidney pelvis and the proximal end of the ureter, with moderate ptosis of the right kidney. A barium enema, with films made during fluoroscopy as well as before and after evacuation of the enema, revealed the barium to pass through the entire colon. The terminal ileum was not visualized at this time. There was a localized, persistant deformity of the cecum in the region of the ileocecal valve (Fig. 1). There also appeared to be a distortion and deformity in the mucous membrane pattern. Films made four and six hours later seemed to indicate that the terminal ileum was reasonably normal. An upper gastrointestinal series revealed nothing unusual. The roentgenologist concluded that the deformity in the region of the cecum was probable carcinoma.

Fig. 1. Print of roentgenograph showing defect in cecum.

DR. A. H. WELLS: The case is now open for diagnoses.

PHYSICIANS: Carcinoma of the cecum, actinomycosis of the appendix and cecum, tuberculosis of the cecum, amebic granuloma, ulcerative colitis, regional ileocolitis and pelvic tumor.

From the Department of Pathology and Intern Training Program, St. Luke's Hospital, Duluth, Minnesota.

Dr. A. H. Wells: Dr. Moses Barron is right. This is a case of regional enteritis. What led you to make this diagnosis?

Fig. 2. Mucosal surfaces of terminal ilium and adjacent cecum.

Dr. M. Barron: Carcinoma is very unlikely because of the twelve-year history of symptoms. Actinomycosis and tuberculosis are possibilities, but the course of the disease does not fit either one. The patient's age and duration of such symptoms as lower abdominal cramps, diarrhea, weight loss and anemia points to a diagnosis of regional enteritis.

Dr. C. H. Mead: The patient was prepared for operation, which was performed on June 24, 1948, at which time a resection of the terminal ileum, cecum and a portion of the ascending colon was performed. The patient appears to be cured to date.

Dr. A. H. Wells: The specimen consisted of a segment of terminal ileum, measuring 14 cm. in length, and a 13 cm. segment of ascending colon with the cecum (Fig. 2). There was a diffuse hard, rubbery, thickening of the wall in the terminal ileum, beginning 5.5 cm. from the ileocecal valve and extending onto the cecum to involve the adjacent 3 cm. of the latter. The mucosa of the involved terminal ileum and the cecum had a roughened heaped-up, cobblestone appearance with no evidence of ulceration or tumor masses. The attached mesentery revealed several firm lymph nodes measuring from 0.3 up to 0.9 cm. in diameter.

The microscopic examination revealed almost complete destruction of the mucosal glands of the ileum, which were replaced by very cellular and congested, vascular scar tissue with dense lymphocytic, plasma cell and neutrophilic infiltration in all layers (Fig. 3). There was some hypertrophy of the mucosal glands in the cecum with no evidence of malignancy. Sections from the lymph nodes revealed both acute and chronic inflammatory changes. A diagnosis of regional enterocolitis was made.

Discussion

Dr. H. H. Joffe: We wish to present briefly four additional cases out of 93,145 admissions to this hospital from January 1, 1936, to August 1, 1948. These cases beautifully illustrate the difficulty in differentiating regional enteritis from acute appendicitis, intestinal obstruction and ulcerative colitis.

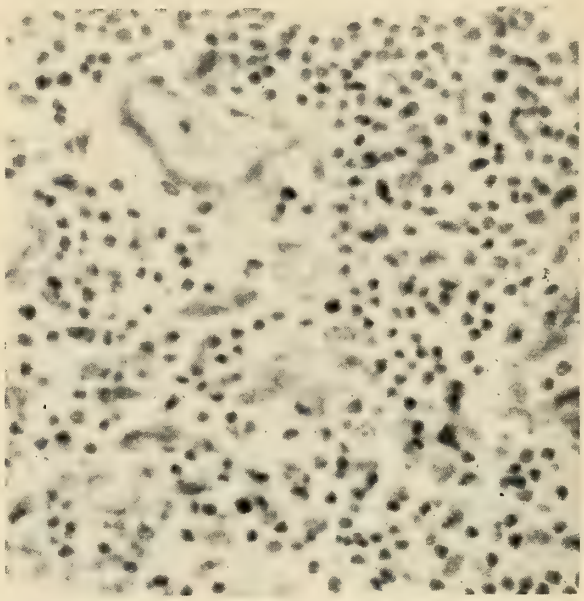

Fig. 3. Photomicrograph of nonspecific vascular granulation tissue in mucosa of ilium.

Case No. 39068.—A twenty-one-year-old waitress with a history of intermittent crampy upper abdominal pain and malaise for five weeks duration was placed on an ulcer regime with some relief of symptoms for a few days. While on her way to work one morning, she was seized with severe abdominal pain radiating into the right lower quadrant. There was also giddiness, weakness, nausea, vomiting and profuse perspiration.

Physical examination revealed diffuse tenderness and rebound tenderness in the right lower quadrant. There was a slight fever of 99.6° F. The hemoglobin was 11.5 grams, with a red blood cell count of 4,370,000. The white blood cell count was 27,250 with 90 per cent neutrophiles. The urinalysis was negative.

A laparotomy for acute appendicitis was performed. The appendix was found to be normal and was not removed. A remarkably thickened, firm terminal ileum was resected with an end-to-end anastomosis. There has been no recurrences of regional enteritis after one year and three months.

Case No. 43074.—This twenty-two-year-old woman gave a history of crampy intermittent abdominal pain, weight loss of 30 pounds and diarrhea amounting to five bowel movements a day, all of a year's duration. There was occasional vomiting, and one evening she experienced sharp lower abdominal pain, nausea and vomiting, and over a period of five days there was no passage of fecal material.

Physical examination revealed an emaciated female with visible peristaltic waves in the upper abdomen.

There was moderate generalized rigidity and marked tenderness and rebound tenderness. There were no palpable masses. The hemoglobin was 11.5 grams with a red blood cell count of 4,620,000. The white blood cell count was 14,750 with 81 per cent neutrophiles. The urinalysis was negative.

An ileocolostomy was done because of the patient's poor condition. There was a cicatricial mass in the lower ileum with proximal dilated viable bowel and no "skip areas." A resection with an end-to-end anastomosis was done at a later date. The patient has now been free of symptoms for two and a half months.

Case No. 40796.—This thirty-eight-year-old man gave a history of episodes of diarrhea and lower abdominal crampy pain for five years duration. The episodes of diarrhea occurred about three times a week with ten to twelve stools daily, but there was never any blood or mucus. There had been an appendectomy several years before.

Physical examination revealed tenderness in the right lower quadrant with a fever of 99.8° F. There was no anemia. The white blood cell count was 14,950 with 77 per cent neutrophiles, and the sedimentation rate was 49 mm. per hour (Westergren). The urinalysis was negative. A chest plate was negative and a gastrointestinal x-ray study led to the conclusion of regional enteritis involving the terminal ileum.

A short circuiting procedure was done, with a resection at a later date. The patient has been free of symptoms for nine months.

Case No. 17493.—This fourteen-year-old girl gave a history of diarrhea with several bowel movements during the day and night for the past three months. There was loss of appetite with a loss of 15 pounds in weight. Two months prior to admission there were episodes of vomiting which occurred two to three times a week, usually after meals. One day prior to admission she experienced cramp-like upper abdominal pain which was located to the left of the umbilicus.

Physical examination revealed an undernourished and dehydrated girl, with abdominal distension and tenderness to the left and slightly below the navel. There was no fever or anemia. The white blood cell count ranged up to 13,300 with 88 per cent lymphocytes. Stool examinations revealed no ova, parasites or acid fast bacilli. There was, however, 1 to 2 plus occult blood with moderate numbers of pus cells and mucus. The urinalyses were negative. A chest plate was interpreted as negative, and a gastrointestinal series revealed a negative colon and terminal ileum.

The patient was closely observed for several days, and an exploratory laparotomy was done with a resection of the terminal ileum and a lateral anastomosis. There has been no recurrence of symptoms for twelve years and four months.

Terminology and Etiology

Dr. H. H. Joffe: The nomenclature is confused by such multiplicity of terms as regional ileitis, regional enteritis, terminal ileitis, acute and chronic ulcerative ileitis, phlegmon of the ileum, nonspecific ileocolitis, chronic interstitial enteritis, ileocecal pseudotumor, infective granuloma, sclerosing and stenosing ileitis, nonspecific intestinal granuloma, Crohn's disease, cicatrizing enteritis and a host of others. The term regional enteritis has been accepted widely for many years and is nonspecific as to location and etiology, all desirable features for general acceptance until the etiology is known.

A lack of knowledge of the causative factor is essential to a diagnosis of this clinical entity.[30] Practically all types of agents have been incriminated, such as: B. coli,[19,34] B. dysenteria,[40] anaerobic streptococci,[35] Aerobacteria aerogenes,[25] tubercle bacillus,[40] Mycobacterium Johnei,[51] bacterial toxins,[20] viruses,[48] Entamoeba histolytica,[11] parasites,[2] achylia gastrica,[40] allergy,[32] trauma,[33] nonspecific inflammation of the appendix,[41] impairment of blood supply[5] and interference with the lymphatic supply.[42] In spite of the heterogenous group of agents, no specific organism or single etiological factor has yet been recognized.[4,40]

Incidence, Sex and Age

Brown and Donald[6] reported a total of 178 cases seen at the Mayo Clinic between 1922 and 1940 with 114 cases in the four-year period between 1937 and 1940. Fallis[21] found one case in 195,000 admissions to the Henry Ford Hospital during the fifteen-year period prior to January 1, 1933, and thirty-two cases out of 180,000 new patients during the ten-year period between 1933 and 1943. The foregoing signifies either an increase in the incidence of the disease or perhaps a sharper clinical recognition.

The disease affects principally young adults with approximately equal sex distribution in two large series[6,34] totaling 233 cases. However, in a review[40] of 393 cases in the literature, 56.6 per cent were males and 43.5 per cent were females. By combining two large series[6,34] totaling 233 cases, we find 78.1 per cent occurred under forty years of age, which closely corresponds with 79 per cent in another review of 382 cases in the literature.[40]

Pathology

The pathologic changes vary with the stage of the disease. They consist primarily of ulcerative, exudative and proliferative inflammatory stages resulting in a cicatrizing granuloma with obstruction or fistula formation.[1,3,4,7,12,14,28,34,37,39,45,46,47]

In the early stage of the disease, the segment of bowel is hyperemic and swollen. The serosa is blotchy or granular, bleeds easily, and may be covered with a plastic fibrinous exudate. The mesentery is likewise edematous, thickened and inflamed, with enlargement of lymph nodes which may form various sized tumor masses. Areas of normal bowel between sharply defined diseased segments, the so-called "skip areas," may be present. The mucosa reveals ulcerations which are usually located along the mesenteric border and lie in the long axis of the intestines.[14,39,46,47] As the disease progresses, the submocosa and, to a lesser extent, the muscularis are the seat of marked inflammatory, hyperplastic and exudative changes, with edema, fibrosis and lymphocytic

infiltration which result in an enormous thickening of the bowel wall, producing a rubber hose consistency. These changes are finally replaced by a fibrostenotic process, with narrowing of the lumen and dilatation of the proximal segment of the bowel. The serosa may exhibit tubercle-nodule-like structures which are often mistaken for tuberculosis. These lesions are described by Warren and Sommers[49] as being diagnostic and are found in the mesentery, lymph nodes and liver as well as throughout the involved segment of gut wall. The mesentery of the affected segment is greatly thickened and fibrotic. The mucosal ulcerations tend to perforate with resultant abscesses and fistula formation.[1,7,12,14,28,37,39,46,47] The latter may communicate internally with adherent loops of bowel or bladder, or externally with the skin surface through the abdominal wall, or any combination may result.[39]

There are no specific microscopic features in the various stages except varying degrees of acute and chronic inflammation with variations in the predominence of neutrophiles, lymphocytes, mononuclear cells, plasma cells and fibrocytes. In the earlier stage, the lesion is more diffuse, involving mainly the mucosa and submucosa. In the latter stages the inflammatory reaction is more focal in character. The presence of giant cells is quite striking in some cases and is probably responsible for the erroneous diagnosis of tuberculosis.[14]

The terminal ileum is by far the favorite site of involvement, but any part of the bowel from the jejunum to the sigmoid may be affected. In one series[50] of 131 cases, 75 per cent involved the terminal ileum, while in another series[6] of 178 cases, the lower part of the ileum with extension into the colon constituted 92 per cent of the cases. In a review of the literature[40] totaling 462 cases, the terminal ileum was involved alone or with extension into the cecum and ascending colon in 79.6 per cent of cases. On rare occasions the lesions are found in the jejunum, cecum, and ascending and transverse colon alone or in combination with involvement of the ileum.

Symptoms and Signs

The clinical picture may be divided into four stages: (1) acute, (2) irritative,[31,39] (3) obstructive and (4) fistula.[3,4,12,14,15,21,47] The acute stage is often diagnosed as appendicitis because of right lower quadrant pain and tenderness, nausea, vomiting, fever and leukocytosis. In two series[9,28] totaling ninety-four cases, a previous appendectomy had been performed in 40 per cent of cases. In the irritative stage, the symptoms of crampy diarrhea, with blood and mucus in the stool, frequent attacks of colic, low grade fever, anemia, inanition and weight loss, simulate ulcerative colitis and may be present over a long period of time. Not infrequently, a boggy abdominal mass can be palpated in the right lower quadrant.[39] Remissions are rather common in the first two stages.[3] As the fibrostenotic process increases, the symptoms of severe abdominal cramps, borborygmi, distension with an increase in the severity of the anemia and more prounounced weight loss, complete the clinical picture of the third or obstructive stage. Complete obstruction is rare, but obstructive phenomena are present at some time during the course of the disease in about one third of the cases.[21] Dickinson and Zimmerman,[15] however, reported a case of acute intestinal obstruction in the absence of any antecedent history of abdominal disease. The fourth or intractable fistula stage is often referred to as a sequela or complication.

In an attempt to summarize the frequency of the various symptoms, we have taken the liberty of combining four series[9,28,30,44] totaling 256 cases, with the results found in Table I.

TABLE I. SYMPTOMS

Symptom	*Number*	*Percentage*
Abdominal pain	212	82.8
Weight loss	186	73.4
Diarrhea	143	55.8
Fever	139	54.3
Palpable abdominal mass	127	49.0
Anemia	104	40.6
Fistulas	64	25.0

The duration of symptoms varies greatly, and in a series[44] of 55 cases, varied from one month to fifteen years, with 52.7 per cent having had symptoms for less than one year.

Diagnosis

The diagnosis of regional enteritis can only be made by a thorough investigation of the gastrointestinal tract.[7] The symptoms of recurrent attacks of abdominal pain, diarrhea, weight loss, chronic partial intestinal obstruction, accompanied by a persistent low grade fever and anemia, especially in young individuals, are strong clinical proof.[24,46] Roentgenologic studies can usually confirm the clinical diagnosis and are repeatedly referred to as the most important single diagnostic aid.[6,7,8,12,28,29,31,39,46,47] In one series[6] totaling 178 cases, a barium enema revealed evidence of the disease in 124 cases, with seven additional cases diagnosed by a barium meal for a total of 131 (74 per cent).

Kantor[29] states that the following are the chief roentgenologic signs:

1. A constant filling defect in the ileum just proximal to the cecum.
2. An abnormality in the contour of the last filled loop of ileum.
3. Dilatation of the ileac loops just proximal to the lesion.
4. The presence of the "string sign" which appears as a thin slightly irregular linear cotton string like shadow, extending from the region of the last visualized loop of ileum through the entire extent of the filling defect and ending at the ileocecal valve.

The "string-sign" of Kantor, though characteristic, is not pathognomonic and may be present in other stenosing processes.

Regional enteritis is often confused with and must be differentiated from appendicitis, tuberculous enteritis, ulcerative colitis, amebiasis, bacillary dysentery, diverticulitis, Meckel's diverticulum, neoplasm of the ileum, sprue, parasitic infections, actinomycosis, syphilis, car-

cinoma and lymphoblastoma.[1,7,8,12,14,16,28,31,34,38,39,40,46] A carefully taken history and a thorough physical examination, aided by roentgenographic studies, sigmoidoscopic examination and laboratory tests, will usually result in a correct diagnosis.

Treatment

The method of treatment varies somewhat with the stage of the disease. In the presence of an acute process or exacerbation it is unwise to institute any operative procedure unless there is obstruction.[1,39,47] In the acute stage the diagnosis is often made by abdominal exploration because of the mistaken diagnosis of acute appendicitis. In such cases, if the appendix is not involved, it should not be removed because of the danger of fistula formation.[38] Medical management has little to offer in the more chronic forms and operation is the accepted treatment of choice if a cure is to be expected.[1,6,7,12,14,22,24,30,34,38,40] There is, however, some difference of opinion as to the method which should be employed. Involvement of the lymph glands and failure to recognize the characteristic "skip areas" are the chief source of recurrences.[22,34] It, is therefore, essential that the surgeon examine every inch of the intestine before attempting any surgical procedure.

In a review of the literature,[40] out of 290 cases in which a resection was done, 67.0 per cent showed a complete recovery, 5.8 per cent had partial recovery, 3.8 per cent showed no improvement, and there were 6.2 per cent recurrences, with 7.2 per cent deaths. In eighty-eight cases in which a short circuiting procedure was done, 30.6 per cent completely recovered, 11.3 per cent showed a partial recovery and 5.7 per cent had no improvement; however, there were 28.4 per cent recurrences and 7.9 per cent deaths.

It is quite obvious from the foregoing data that the recurrence rate is considerably less when a resection is done regardless of whether it is a one-stage or two-stage procedure. The mortality is less with a resection than with a short-circuiting operation. Furthermore, the percentage of complete recovery is greater with a resection. These conclusions are not agreed to by all authorities.[22]

Summary

We have presented five cases of regional enteritis and a concise review of the literature.

The preoperative diagnoses in the five cases included acute appendicitis, carcinoma of the cecum, intestinal obstruction, ulcerative colitis, and tuberculous enteritis. They were apparently cured by resection of the involved area with no recurrence of symptoms over a period varying from one and a half months up to twelve years and four months.

History of Medicine In Minnesota

NOTES ON MEDICINE IN FREEBORN COUNTY, 1857—1900

ANDREW GULLIXSON, M.D.
Albert Lea, Minnesota

(Continued from September issue)

He then also writes of the county seat contest between Albert Lea and Itasca, in which "Dr. A. M. Burnham, who possessed rare energy and enterprise, was the genius of the place." This was a contest which was to be settled by a horse race between the Itasca Fly and Albert Lea's Old Tom. He relates:

"The race track was made on the smooth prairie, with two paths this time and so far apart that it was supposed Old Tom could not jump across into the Itasca Fly's track again. This time Old Tom had a rider. When the word was given Old Tom made for his antagonist's track and gained the lead, and when the pole was reached Old Tom was given the race by forty feet. Itasca folk had bet everything they had on the race. Those who lost their money and their cattle, horses and plows, chairs, pigs, chickens and knives, coats and hats, and guns and boats, began to get tired of Itasca and its sure thing, and voted for Albert Lea. The county seat question was settled by Old Tom, and Itasca collapsed as a townsite.

"In 1857 people got 4 pounds of brown sugar for a dollar. Syrup was $1.50 a gallon and salt ten cents a pound. Those who had traps sold coon skins for $3.50 to $4.00 apiece, muskrat skins for forty cents, and mink skins for $3.50. I remember our folks borrowed a setting hen long enough for her to hatch. There were swarms of mice and no cats. I remember an acquaintance allotted one to us from an expectant that gave promise of a small supply. When the word came, I (eleven years old) walked after it. I was not invited to dinner and so I walked the twenty-five miles on an empty stomach.

"It was considered proper to steal wood from the land speculators and from government lands. A neighbor of ours became discouraged on account of the depredations of the blackbirds and left his farm. One Sunday we went up there to look around and also to pick strawberries. The people from the prairie were thick as hops. Axes, crosscut saws, crowbars, and hammers were all doing their best. D-.R.- and Dr. Burnham got the best of the plunder, and those old veterans took plain saw logs."

The account goes on to tell of Indians coming off their reservations and striking camps in the settlements and proceeding on begging and stealing expeditions, and how an old trapper who knew how to handle them would roughly break them up.

"When the Rev. McR- preached, every one attended though everything was primitive in the extreme. On one occasion old Charles M., who was drunk, attended the meeting. Rev. McR- had told a story about a boy to illustrate some point. Old Charley wanted to know what had become of the boy, and called in an excited voice, 'I will give you a half a cheese if you will tell me what became of that boy.' The good man stopped his sermon and told old Charley the story. On another occasion, when the minister had assigned the hymns and the audience had sung them in a key a few octaves too high, he announced his text, and they sang that, too, in the same high screechy chord. This made the royal old man smile but it did not disturb him."—*Standard,* May 11, 1900.

In many instances the professional education of the early pioneer doctor was obtained by reading and practicing under a preceptor. On the preceptor's approval his pupils would begin their own private practice. After the license law was passed

in 1883, these prospective doctors usually attended medical schools and received certificates. The leaders in pioneer medicine, those who had taken both preliminary academy and college courses and held degrees from the leading medical schools, attended with surprising regularity the Minnesota State and the American Medical Association meetings. Medical ethics were held in high regard by these noble gentlemen, and they must have been masterful and dignified in council and at the bedside. They knew the art of medicine, their pharmacology, and their therapeutics. Their armamentarium, both as to proven drugs and surgical instruments and appliances, was of course, limited. The keen rivalry of the different schools—eclectic, homeopathic, and allopathic—had brought to light many effective tricks in compounding the indicated and delicately balanced medicaments. The king and the queen of all medicines were used in the early day in the form of laudanum and the infusion of leaves of digitalis. Laudanum with whisky was used liberally as an anesthetic in minor surgery and for extraction of teeth by turnkey. Infusion of digitalis was prescribed, with or without blue mass, when indicated and was continued until it resulted in a "puke or a purge." After stropping it on his boot, a doctor would use his jack knife, on occasions, to open an offending abscess and likewise for a hurried trachectomy.

Transportation in the early days was a problem for the pioneer doctor. A saddle-horse, with saddle equipped with saddlebags for drugs and supplies, was used if destinations led toward passable roads for horse and rider; otherwise, the lurching ox-cart was used. Later, with improved trails, the doctor would drive a span of horses hitched to a buckboard; and finally, he was spinning over country roads in an elegant covered buggy, drawn by a span of well-bred, spirited horses.

There were many deaths and injuries caused by the explosion of lamps from excessive residual gas in the kerosene. Injuries or deaths from runaways, freezing, drowning, suicide, and insanity were not uncommon. But the greatest tragedies were those resulting from preventable diseases, such as diphtheria and scarlet and typhoid fevers. One who has never entered the room of a typhoid fever patient, defenseless against flies, on that long lonely road for weeks, lying dehydrated in muttering delirium, with a distended rose-spotted abdomen and nervous twitching wrist with its soft dicrotic pulse, and a foul-coated tongue, has missed, fortunately, an unforgettable experience.

From the time of the panic of 1857 to the issuing of stable greenback currency at the beginning of the Civil War, there was no money. Immigration continued in increasing numbers, but the new settlers were, for the most part, penniless. Barter was the only means of trade. No doubt the pioneer paid in part his delinquent doctor bills by bringing him dabs of butter, eggs, hay, oats, and corn, and skins of mink, coon, and muskrat, or perhaps a bundle of home-carved ax-handles which the doctor could dispose of in his drug store. But usually his accounts remained unpaid through the years.

Largely for these reasons, nearly all the early pioneer doctors owned and operated drug stores as well as large farms. A few became enthusiastic breeders of cattle and swine and particularly trotting horses, both for racing and for use on the roads.

The leaders among the very early pioneers came from the East and were usually well educated. Academies and colleges in those days subjected their students early to the old classics and to the best in English literature. It is easily discerned from their speeches and their contributions to the press that they had dipped deeply into the ethereal spring. Some of them, including doctors, were orators who could make the king's English walk in majesty and grace. Some well-educated farmers,

too, could deliver Fourth of July orations that would stir the soul. The weekly newspapers carried full page chapters of installments of the best novels, as well as columns on current events. In the absence of libraries in those days, anyone with a dictionary could help himself to a lot of satisfactory amusement, as well as a very good knowledge of the English language, by spending a part of the long winter evenings in this pursuit.

Dr. A. C. Wedge, in his tribute to the Hon. William Windom, late Secretary of the Treasury, in a beautifully written encomium, not only portrays the outstanding character, rugged honesty, and integrity of his old friend, but he also reflects the same in himself (*Albert Lea Enterprise,* February 5, 1891).

The early men of medicine were versatile. They were civic-minded leaders. Inured to hardships themselves, they never forgot to extend a kindly comforting hand to the despairing, nostalgic mother and family of the struggling immigrant in times of stress. They were ministers, counselors, psychiatrists, lawyers, bankers, and doctors all in one. Their hearts were in medicine and dutiful service. Their hobbies were politics, farming, and stock breeding. Their amusements were travel, reading, memberships in scientific and literary societies, hunting, fishing, and fast-trotting horses. The gospels of Pasteur, Lord Lister, Koch, Klebs, Loeffler, Virchow, Bilroth, and famous men of more recent years were not theirs to turn to and contemplate; and they stood as helpless before the ravages of diphtheria, scarlet fever, and typhoid fever as they did before the storms, blizzards, and grasshoppers. They drew a tough assignment in a tough place. They redeemed the pledge they had made.

"The man who is able to put all he owns on earth into one canvas-covered wagon—wife, children, household goods, all—and move with slow pace into what has been called the Wilderness of the West, is doing a work for himself, his family, for civilization, his country, and his God that can never be fully known or its influence told, until the final disclosure."—Senator C. S. Pomroy, Kansas, May 5, 1862.

Public Health and Sanitation

After the legislative act of 1872, setting up a State Board of Health and Vital Statistics, we find in the board's report that the number of births in that year was 322. Of these, 164 were Norwegians; seventy-nine, Americans; fourteen, Germans; thirty, Danes; twenty-six, Irish; three, Swedes; two, English; and four, Canadians.

In 1874, there was an epidemic of smallpox, scarlet fever, and typhoid fever. In 1873 a case of leprosy was treated by Dr. J. Froshaig, and records reveal that with the assistance of Dr. Wedge he amputated a part of a patient's foot.

The following is a notice from the department of the State Board of Health dated April, 1874:

"To the Albert Lea Board of Health: Please keep me informed of diseases prevailing and of sanitary work in your district. May I suggest careful sanitary survey of your town including water supply, wells, springs, and to see that they are not contaminated. The Board suggests that you collect regular statistics of births and deaths in accordance with registration laws."

In January, 1891, city physician H. H. Wilcox reported thirty-two deaths, itemized as follows:

"Consumption, nine; pneumonia, four; membranous croup, three; cancer of stomach, two; meningitis, one; appoplexy, one; typhoid fever, two; puerperal sepsis, one; paralysis of the brain, one; unknown, five; total, thirty-two. Of these, seven were over fifty years of age."

Report on "Vital Statistics" for 1895:

"Deaths, native, 105; Norway, thirty-three; Denmark, seventeen; Germany, five; Ireland,

eight; Sweden, two; England, two. Cause of death: consumption, ten; heart disease and pneumonia, eighteen; inflammation of the bowels, seven; diphtheria, seven; cancer, six; appendicitis, four; typhoid, three; meningitis, three."—*Enterprise,* January, 1895.

Dr. Ludvig Hektoen in collaboration with a historian in *Studies and Records* (vol. 1, pp. 19-21), has this to say about infectious and contagious diseases among Norwegian immigrants: "Their spread was advanced by the unsanitary conditions and practices of many of the early pioneer settlements, where nothing was done to disinfect or properly dispose of the highly infectious discharges. Not even outhouse toilets were in use in the early days on the frontier; windows were not screened; few pioneers dug wells, and those who did, oridinarily made very shallow ones; water was taken from streams and springs or lakes, stored in barrels and often contaminated." Dr. Hektoen and his collaborator relate that among the Norwegian immigrants "not only malaria and cholera, but many other kinds of diseases, were prevalent in pioneer settlements, including pneumonia, typhoid fever, and tuberculosis." "One of their most interesting gneralizations is that "Fewer (Norwegian) persons seem to have died of tuberculosis in those early days than later," and they conclude that this high mortality rate among the Norwegian people in America, even up to our own day, is probably the heavy penalty for the poverty, squalor, and hardships of pioneer days." These observations are entered here because immigrations to Freeborn Country from very early days have been preponderantly Scandinavian.

In 1874 there was an epidemic of smallpox, scarlet fever, and typhoid fever. In 1881, a smallpox epidemic occurred and isolation was ordered.

"Scarlet fever, a severe epidemic. Three children in one family succumb. It should be noted that scarlet fever is equally contagious as smallpox. It is readily communicated through clothing and for a considerable distance in the air. Greatest care should be exercised to keep patients isolated and prevent all visitors except physician—Board of Health."—*Standard,* August, 1881.

The 1887 session of the legislature provided for reports of vital statistics and also enacted the first meat inspection laws:

"Each local board of health to set up an inspection service to pass on cattle, swine, and sheep, twenty-four hours before slaughter and to certify same for human consumption."

Reports in the newspapers show that on one day in 1870 seven hundred teams of oxen and horses were counted on the streets of Albert Lea. The custom was to unyoke and unhitch on the streets, and tie the animals to the wagons, supplied with hay and feed. The decomposition and filth from all the litter on the streets was unbearable, and the muck in the streets rendered them almost impassable. The Board of Health ordered the segregation of teams away from the main streets, passed ordinances relating to carelessly constructed privies, made provisions for safer dumping grounds, and declared the drainage from these to be a nuisance. Perhaps this mounting offense to sight, smell, and general transportation was what induced the rugged editor at that time to spew this one, which also involved a serious health problem:

"We do not have many rattlesnakes in this section, but we do have any amount of whisky. For fear they may take a trip over here, note that it would poison a rattlesnake if one bit some men we know around here."—*Enterprise,* April, 1874. "The smell from the dumping grounds this side of the old mill is anything but pleasant to the olfactory nerves. Those who have charge of the matter are exceedingly derelict of duty."—*Standard,* July, 1891.

Not until May, 1894, was a petition made by the Board of Health for public dumping grounds in Albert Lea. In 1894 Dr. J. M. Todd, president of the board, pronounced the slaughterhouse and packing facilities to be a nuisance the way they were operated. There being no sewers provided, it was impossible to run it in a cleanly manner, and he advised that it be moved outside the city limits.

In May, 1893, at the request of Dr. J. M. Todd, president of the Board of Health, Dr. C. N. Hewitt, president of the Minnesota State Board, visited Albert Lea. He investigated the sanitary conditions of the city and inspected nuisances about which there were complaints. A public meeting was held to listen to an address by him. "With pungent facts, forceful argument, and key wit, he proceeded to show how cholera, smallpox, and similar diseases were brought to America, and how easily they spread. He made clear the thoroughness now being adopted by national and state officials in regard to vaccination. He also made a plea to abolish privy vaults and cesspools. The city should no longer permit them in our midst. He advised against sewage being emptied into either of the two lakes."—*Standard,* May 17, 1893. There were no regular county physicians in Freeborn County's early days. The poor were attended by local physicians, who presented annual bills to the County Commissioners. During the first half of the 1870's, the total annual payments averaged from 150 to 250 dollars. The epidemics of diphtheria, scarlet fever, and typhoid fever through the 1870's and 1880's were at times frightening in their ravages. A pioneer physician told the writer forty-five years ago that it was his honest belief that antitoxin in cases of diphtheria in those days would have been unavailing because of the severity of the disease, with deaths often coming in twenty-four to thirty-six hours.

Hospitals

Not until 1894 was any attempt made to provide hospital facilities. In that year Dr. J. M. Todd publically advertised for hospital purposes, "a building thoroughly equipped with trained nurses, electric and medical baths, and every convenience for treating chronic and surgical diseases." The following year, 1895, Dr. Frank A. Blackmer erected a building on his residential property, where he equipped and operated a ten-bed hospital.

"A public meeting was called in the courthouse to see what could be done about building a public hospital. Dr. A. C. Wedge was chosen president and Dr. H. H. Wilcox, secretary. Dr. J. M. Todd stated that all physicians in the city wanted such a public hospital, and Dr. Wilcox thought that a public hospital was an absolute necessity. All favored purchasing Dr. Todd's hospital with its ten beds, and a committee was selected either to purchase Dr. Todd's hospital or make arrangements for procuring another."—*Enterprise,* November 19, 1896.

Nothing came of this venture, and in August, 1897, Dr. Wilcox equipped a part of his large residence and operated his own private hospital. In the meantime, Dr. J. M. Todd in April, 1897, sold his fine hospital and went to New York City to enter the business world. But even as Dr. Todd sold his hospital, another was being built under the direction of Dr. Henrik Nissen. He erected a large three-story brick building on south Broadway in Albert Lea, well constructed with accommodations for a large pharmacy on the ground floor and offices, operating room, and about twelve beds on the second and third floors. Thus in 1898, Albert Lea was provided with three private hospitals. In March, 1898, Dr. H. H. Wilcox wrote from Chicago, where he often went to observe and learn, as follows:

"Without doubt Albert Lea ought to have one good general hospital where all physicians might have designated days for operations. Such an institution with physicians organized

into a local society would be of much value to the city, southern Minnesota, and northern Iowa. No one wanted such an institution more than I. Now that I have a good place of my own, I must work to make it pay; and hence, my attendance here now."—*Enterprise*, March, 1898.

These small hospitals served the most pressing needs, but they did not prove financially successful and were abandoned by 1905. In December, 1905, a meeting of citizens was called to consider the hospital project. The result was the organization of the City and County Hospital Association, with a board of directors given power to act. Funds were raised and the Wilcox hospital was taken over on a rental basis for a period of five years. In the meantime the campaign was on, public interest was surprisingly great, and early in 1912 the Albert Lea general hospital project was solved for the immediate present by moving all patients into the new Naeve Hospital of the City and County. Its name was derived by reason of a generous gift of home and grounds from a wealthy widow, Mrs. Naeve. At this writing a new addition is being completed which will supply one floor for surgery and approximately sixty beds, giving a total of 140 beds.

Education and Health

Early public education provided no instruction relating to health. In 1857 the population of Albert Lea was 285 and the total of the county was 2,486. The Albert Lea district provided a levy of $400 for a school building. Sixteen rural districts were organized in 1857. Some townships had several; others, none; but in almost every settlement schools were sustained in a private way. In October, 1857, the records show the total school funds available to be $398.96, or exactly $1.70 for each pupil. Compared with the school programs of today it reveals a sorry situation.

Knowledge as to health had to come from the doctors, either through private consultation or by attendance at forums, societies, and lodges, where they were active leaders. Dr. Elizabeth Stacey afforded active and effective leadership in organizing temperance societies that met regularly and in earnest endeavor and were of much benefit. But to get to their doctors and to these meetings beyond a distance of five miles, transportation by ox-cart required a day and a night's travel for only a good yoke of oxen could travel up to twelve miles in a full day. Hence, for the most part the early rural pioneer was on his own in matters of health. Self-medication was practiced to a high degree and often with great rivalry. To reveal the extent to which this was carried on, the autobiography of a county doctor in 1873 contains the following excerpts that reveal the assumed professional wisdom of some folks in matters of health and disease:

"Deacon Rogers he came to me.
'Wife is going to die'! said he.
'Twenty old women with remedies now
Bother my wife all day through.
Sweet as honey, bitter as gall,
Poor old woman she takes them all.'

"Mrs. Rogers lay in her bed,
Bandaged and blistered from foot to head.
Bottles and saucer, spoon and cup,
On the table stood bravely up.

"Physics of high and low degree;
Calomel, catnip, bone-set tea;
Everything a body could bear,
Excepting light and water and air.

"I opened the blinds, the day was bright;
And God gave Mrs. Rogers light;
I opened the windows, the day was fair,
And God gave Mrs. Rogers air.

"Bottles and blisters, powders and pills;
Catnip, bone-set, syrup of Squill's;
Drugs and medicines high and low;
I threw them as far as I could throw.

"'What are you doing'? my patient cried;
'Frightening death'! I cooly replied;
'Are you crazy'? a visitor said;
I flung the bottles at her head.

"Deacon Rogers he came to me.
'Wife is coming around', said he;
'I really think she will worry through,
She scolds me just as she used to do'.

"All the people have pooed and slurred;
All the neighbors have had their word!
'Your wife,' said I, 'has God's good care
In his remedies, light, water, and air;
All the doctors beyond a doubt
Couldn't have cured Mrs. Rogers without.'

"The Deacon smiled and bowed his head,
'Then your bill is nothing,' he said.
'God's be the glory, as you say,
God bless you, doctor, good day! good day!'"

Medical Societies

Freeborn County was late in promoting the organization of its medical men. Dr. Wedge had, however, called the fraternity together, perhaps under the authority of the forum he founded in 1857 and called the "Albert Lea Senate." The call stated the "purpose of counseling together in good fellowship." October, 1898, the Albert Lea District Medical Association was organized, whose membership comprised doctors of Freeborn County and of Worth and Winnebago Counties in Iowa. Dr. A. C. Wedge was chosen president; Dr. W. H. Jones of Forest City, Iowa, vice president; and Dr. H. H. Wilcox, secretary. Nineteen members were present at the meeting. The membership was later increased by the addition of doctors from Lake Mills and Northwood, Iowa. The Freeborn County Medical Society was organized January 2, 1903, according to the provisions of national, state, and county relationship. Dr. A. C. Wedge was chosen as its first president and served until May, 1907. He was succeeded by Dr. G. W. Barck. He in turn was succeeded by Dr. J. P. Von Berg in 1909, who continued to serve until 1925. Dr. H. H. Wilcox was the first secretary and was succeeded in 1904 by Dr. G. A. Stevenson. As Dr. Stevenson exercised his usual veto and refused to serve, Dr. O. E. Burton was elected. Dr. W. L. Palmer was the first vice president. Total membership at the organization meeting was fifteen.

(To be continued in the November issue)

President's Letter

THE NATION'S HEALTH

The long awaited report from the National Health Assembly, that met in Washington on May 1 to 4, 1948, has finally been published, as released by Federal Security Administrator, Oscar R. Ewing. It is a broad plan and has the endorsement of President Truman, and includes most of the President's earlier health proposals. As was expected, the report as submitted goes beyond the recommendations that had been developed during this four-day conference. Mr. Ewing has also added his own interpretation and recommendations. The document was politically prepared and has been timed so it can be used during the forthcoming campaign, and places compulsory health in the political arena. The report is well-prepared and is packed with governmental health statistics, which the average citizen accepts at face value. Most of the figures are so general that they are misleading and actually could not be supported by scientific facts. After having read the report, one is left with the impression that the Government is going to give the people of our country something for nothing. But, of course, this is never true, as every dollar which is spent by the Government comes from the American taxpayers.

In addition to compulsory health, Mr. Ewing proposes to develop an expanded program of Medical Education, Research, Hospital Construction, Hospital Maintenance, and Community Health Protection. The cost of this proposed program would be boosted to 4.1 billion dollars by 1960, or more than double the present yearly outlay of two billion. Of course, this does not include the cost of compulsory health insurance, which would add many more billions to the taxpayers' bills.

There are several recommendations in the report that one can accept, but as a whole it is unsound and impractical. I would suggest that every physician should secure this report (The Nation's Health—A-Ten-Year Program) and study it carefully. It can be secured from the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. The cost is one dollar.

President, Minnesota State Medical Association

MORE DOCTORS NEEDED IN THE ARMED SERVICES

WHEN the Selective Service Act of 1948 was being considered by Congress, it was proposed that the medical profession be drafted as a matter of necessity. Protestations on the part of the profession against the drafting of members of the profession, which would have been the first time during either war or peace that such a step was taken, resulted in the omission of this provision. The profession virtually assured the Army that sufficient medical men to care for draftees would enlist voluntarily.

The Selective Service Act of 1948 provides that no individual shall be inducted until adequate provision shall have been made for his proper care, including medical care and hospital accommodations.

The Army Medical Department needs some 6,900 doctors. At present, it has about 3,000, including interns. If sufficient enlistment of doctors is not forthcoming in the immediate future, the draft program will have to be slowed up, and if by the time the next Congress convenes there is a dearth of enlisted doctors, remedial legislation will doubtless have to be considered.

The drafting of doctors should not be necessary in the near or distant future. Thousands of young doctors have been allowed to pursue their medical education at government expense, and while perhaps not legally bound to enlist, they are so bound morally. Further, the inducements from the standpoint of rank and pay have been increased, and interns and residents who enlist are permitted to continue training in either civilian or Army hospitals. Doctors who enlist are commissioned as lieutenants and receive $380.00 a month as pay. Similar inducements are offered by the Navy.

It is reassuring to learn that while the Selective Service Act of 1948 designates men between nineteen and twenty as subject to draft, it seems assured that medical students and interns will be deferred until they complete their training. A certain number of premedical students will also doubtless be deferred to assure the graduation of enough medical students in future years.

Not young doctors alone are desired for enlistment. It is understandable that those who were undergraduates during the war period have not had the experience to handle all the army medical needs. Older and experienced men are indispensable. A continuous new supply is also needed to replace those, both young and old, who are daily retiring.

It can be expected that the profession will respond to the present urgent need so that our record for patriotism, in peace as well as in war, will not be broken.

ARE YOUNG SPECIALISTS DENIED A CHANCE?

WE don't often read the *Woman's Home Companion.* However, our attention was called recently by a full-page newspaper advertisement to an article appearing in the October issue by J. D. Radcliff, entitled "Give the Young Doctor a Break." We yielded to a feeling of curiosity and purchased a copy and read the article. This, of course, was in keeping with the purpose of the advertisement.

An introductory paragraph quotes Dr. Allan D. Whipple, a former president of the American Board of Surgery, as follows: "There is no doubt that these young qualified doctors are prevented from demonstrating their ability in a good number of communities by the failure of local physicians to give these younger men opportunity to practice in the hospital or hospitals in the community. Dean Willard C. Rappleye of Columbia College of Physicians and Surgeons is also quoted as saying that this situation is "the greatest waste in medical manpower and skill in our present system of medical service."

The article goes on to state that a young specialist, denied hospital facilities, is unable to make use of his skill, improve himself through the use of the hospital library, build up his practice or

even support his family. This is perfectly true. It relates how in certain localities certain industrial surgeons employed in war industries were prevented from having hospital appointments for a period of five years on entering private practice. It relates the case of a young surgeon in a Pennsylvania manufacturing town who in his first year of practice performed just eight operations and all were on the wives of physicians. The local profession recognized his skill, but their failure to refer patients to him resulted in his leaving town. This is too fantastic for belief. The supposedly pathetic story of Jim who had spent years in acquiring a top-notch surgical training and his difficulties in finding a location so that he was finally forced to accept a $3,600 job as surgical instructor at his alma mater somehow fails to elicit tears. Somehow one feels the temporary job may lead to bigger and better things.

The entire article is tinged with sensationalism and gives the lay reader the impression that the older members of the medical profession are, as a rule, less skilled than the present-day Specialty Board licentiate and through jealousy prevent the young specialist from competing by preventing him from obtaining hospital appointments to the detriment of the public.

How much foundation there is for the accusation, as far as the country at large is concerned, is difficult to evaluate. We do know that it is common practice for established specialists to take young men under their wing and help them get started. While there are doubtless selfish and jealous doctors, it would seem rather exceptional for them to be able to prevent a young potential competitor from obtaining the use of a hospital simply in order to forestall competition. That this should ever occur is, of course, reprehensible.

While the article smacks of sensationalism and is not a picture of the general setup, it affords food for thought. Do we as individual doctors and as organized medical societies do what we can and should to help the specialist or, for that matter, the general practitioner who hangs out his shingle?

County societies in the past have been so fearful of admitting to membership undesirable members of the profession that they have required a period in some instances of a year of practice or several months of investigation before admitting strangers to society membership. Such perquisites as malpractice insurance, hospital staff membership, appointments as examiners for life insurance companies and the like being dependent on county society membership, such requirements have in the past made the beginning of practice the more difficult. Some societies have corrected such unjust provisions in their constitutions.

To become established in a medical practice has seldom been an easy matter. The great majority of doctors have found the building up of a clientele a slow procedure. It has been said with some truth that the young doctor spends his early years trying to get patients and his later years in trying to sidetrack them. An able and well-trained doctor, be he specialist or general practitioner, cannot as a rule expect the local profession to swamp him with patients from the start nor the local public to be waiting to welcome him with open arms. The specialist who has spent additional years in preparation is conceivably more likely to feel restive at the slowness of what may be a normal growth of practice. The training of too many specialists which, as we have pointed out before, has been going on in recent years, only tends to aggravate the seemingly slow process of building up a practice, and with the increased production of specialists in the near future, the tempo is likely to be still further slowed. We contend that the overproduction of specialists is going to prove "the greatest waste in medical manpower." The production of specialists should be restricted.

In view of the scarcity of hospital accommodations, it is conceivable that a specialist or, even more perhaps, a general practitioner on starting practice and having difficulty in obtaining hospital beds for patients might feel he is being discriminated against by the hospitals. All doctors are having the same experience and are liable to entertain an unjustifiable resentment at a fancied injustice.

Some medical societies have been conscious that they have not been of as much assistance as possible to the young doctors opening an office for the first time in their locality, and the need for remedying the oversight is shown in the case of the Ramsey County Medical Society in Saint Paul. Junior memberships were recently established for these new men which entitle them to all perquisites of membership after a brief period

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

COUNTY SOCIETIES DEVELOPING "NIGHT CALL" ARRANGEMENTS

Securing of emergency medical aid at night has long been a source of difficulty and misunderstanding between the public and the medical profession. At the urgent request of the American Medical Association, medical societies throughout the country have been studying ways and means of working out the problems involved.

Incidents of failure to locate or secure the services of a doctor undermine the prestige of the profession, it has been shown. Therefore it was suggested that local physicians' telephone exchanges be established or that there be maintained at local society headquarters a system of rotating night duty together with a list of physicians willing to assume that responsibility.

The subject of "night calls" was discussed at the Council on Medical Service meeting last February in Chicago, when the various methods of handling emergencies were discussed.

Although the law does not compel a physician to respond to an initial call, and the code of ethics allows a physician the freedom of choice in whom he will serve, the public nevertheless *"wants a doctor when it wants him."* Because of the demand for service remedial programs are under study, and a good example is the program being formulated by the Northampton County Medical Society, in Pennsylvania. A group of doctors on the staff of Easton, Pa., Hospital* have formulated a statement outlining their views, which seems a sensible approach.

Refusing Calls Dangerous

Refusal on the part of too many physicians to accept emergency calls, particularly night calls, is a dangerous practice and is becoming a wedge in the attack upon private practice of medicine, the Easton doctors warn. Proof that the problem exists, they say, is evidenced in the nationwide propaganda appearing in newspapers and magazines. After due consideration, the doctors concluded that the problem of night calls is, first of all, primarily a problem of practicing physicians in general practice and internal medicine or related specialties, that physicians should personally see that their patients are covered at all times. These doctors suggest the attending physicians inform patients as to whether they will or will not make night calls and thus give their patients opportunity to choose another physician, should they so desire.

When a physician does not or cannot make a call at night, it is his duty to see that another physician sees his patient, either a colleague or a younger man, according to the Easton doctors. They add that arrangements should be made when the attending physician will be away from home for twenty-four hours or longer. Furthermore, they suggest that when a colleague must be summoned, that the physician himself make the call rather than his patient, who, as a stranger, stands less of a chance of getting medical aid.

Problem Is Local

It has been suggested that a registry be maintained in the centers of the community listing the names of all physicians who have signified willingness to make night calls and that these men should be called in rotation. If this is not feasible, the local society must take the initiative and designate a group of physicians to be responsible for night calls during a specified period.

The prerogative and the duty of finding answers to the community medical needs are, of course, that of the county medical society, since plans will undoubtedly be modified by local conditions and needs. It is agreed that the clamoring of socialistically minded and anti-medical groups must be answered and that the county

*Morris Kramer, M.D., Frederick Ward, Jr., M.D., and Frederick Clarke, M.D., prepared a report of the Easton Hospital plan for the *Public Relations Reporter* of the Pennsylvania Medical Society, July 20, 1948.

medical society is the logical place to begin. It is suggested also that the public be made aware that emergency and night service is available to them, whether it is through an individual working arrangement between patient and doctor, by a registry system or by a roster maintained by the county medical society which has designated a group of members to make night calls.

A notable example of efficient management of the night call problem is the plan being followed in Cleveland. Cleveland physicians have taken the position that "response to emergency calls for help from its citizens is the responsibility of the entire community in its official and unofficial capacities."* Just as police and fire departments handle emergencies and city hospitals maintain ambulance service, the doctors in Cleveland have over a period of ten years maintained a system for caring for emergent needs of their patients and have recorded some of their findings.

Many emergency calls, they have found, aren't really serious; but, on the other hand, they maintain, in most cases, only a physician can determine ultimately whether an emergency exists, hence the need to respond promptly to requests for assistance.

With a well-organized round-the-clock switchboard service, such as would be difficult to maintain without proper facilities, Cleveland physicians have been operating a service which has been a source of help to the public in various ways—by answering individual calls for medical care and by providing also assistance to police and firemen who frequently call the exchange for accidents and sudden illnesses when it is not possible to transport victims via ambulance to a hospital.

Average 8.7 Minutes Per Call

The Academy has found that in a group of 300 emergency calls studied, the average length of time elapsing between the call for service and contact with a doctor able and willing to provide service is only 8.7 minutes. Of the 300 calls, there were fourteen that took an unusually long time due to extenuating circumstances. When these were not counted, the average time to locate physicians drops to 6.8 minutes. At a time when anxious relatives are inclined to translate minutes into hours, this average makes for a minimum of inconvenience and friction.

Cleveland's experience is that it is most difficult to reach physicians between 6 and 7 p.m., when most of them are on the way home. During that hour it has taken the switchboard up to twenty minutes to locate a doctor.

The Cleveland study of emergency cases reveals cases where doctors are needlessly called and has put the service on its guard against exposing doctors to such inconvenience. For example, cases occur where someone has summoned a doctor through the telephone exchange, and, upon arriving, the doctor discovers that the police and several helpful neighbors have also summoned other doctors. There are also cases of drug addicts or chronic drunkards who summon physicians when they really aren't needed. The service seeks to eliminate for the physicians such wasted trips.

Thus it is felt by the Cleveland Academy that although it is not legally bound to maintain its call service and that maintaining it entails a certain amount of sacrifice on the part of the members, the grateful response on the part of the public and the satisfaction that a real and efficient public service is being carried out is rewarding enough to argue for the continuance of the system.

*Bulletin of the Academy of Medicine of Cleveland, April, 1948, Page 7.

MEDICINE FACES CRISIS, DOCTOR HAWLEY DECLARES

Medicine is facing a crisis—either it must act or perish—according to Dr. Paul R. Hawley, former chief of the medical division of the Veterans Administration, who now heads the Blue Shield-Blue Cross national commission. Dr. Hawley delivered a scorching warning to the medical profession at the Conference of Presidents and Officers of State Medical Societies at the AMA Chicago meeting last June when he painted a very discouraging picture of medicine surrounded by forces seeking to overthrow it. The only solution, Dr. Hawley maintains, is the extension of prepayment medical and hospital service—at once.

Dr. Hawley pointed out that medical care is no longer the exclusive prerogative of doctors, that consumers have a great stake in it, as borne out by the discussions at the recent National Health Assembly. Such groups as labor, co-op-

eratives, veterans, colored people and the Physicians' Forum are supporting the contention that compulsory health insurance is the only way to meet the standards of health care set up by the National Health Assembly, that voluntary plans "don't go far enough."

The powerful labor unions, medicine is well aware, have for some time been developing health and welfare programs for workers. Medicine hasn't been consulted in the setting up of a single one! The co-ops are busy with proposals to extend their influence and gain certain controls. Dr. Hawley names men in top positions in health plans throughout the United States and Canada who frankly favor government taking over medicine. Speaking of the co-operatives, Dr. Hawley declares:

"I cannot stress too strongly the fact that this movement has already reached the point where the medical profession has the choice only of making a reasonable effort to meet the requirements of these large groups of consumers of medical care, or of watching the private practice of medicine in this country being rapidly strangled either by co-operative or government medicine."

Need a Comprehensive Plan

What does Dr. Hawley suggest? Well, first of all he wants a comprehensive voluntary insurance plan to meet the public demand. The plan, he says, regardless of cost, will have to offer more than one type of contract, according to what the people want to buy—a contract within the reach of low-income groups that will bear all or part of its costs, and in addition a contract for those large union groups who demand more comprehensive service and are both willing and able to pay for it.

Dr. Hawley also suggested that there be a national service agency, controlled by all participating Blue Shield Plans. Dr. Hawley states positively that he believes no individual, local efforts are going to turn the trick without some national co-ordination. He gives the medical profession exactly three years until heavy financial commitments of the government such as the Marshall Plan and the re-armament program will have eased a little and politicians will be able to work in a health tax. Arguments using logic won't help, Dr. Hawley says. The issue will be decided, not by *wisdom,* but by *emotion*—try as medicine may to educate the public on the issues at stake. Only an accomplished fact—a broad, comprehensive program providing the public with the coverage it wants—will save medicine, Dr. Hawley concludes.

ENROLLMENT TOPS 5,000 IN GENERAL PRACTICE GROUP

With an enrollment now of well over 5,000 members, the American Academy of General Practice (AAGP) is going into its second year as a national organization. Big plans are now under way for the first Annual Scientific Assembly, to be held in Cincinnati at the Netherlands Plaza Hotel, March 7, 8 and 9, 1949.

At that meeting, officers of the Academy who were elected at the first Congress of Delegates, held just previous to the AMA meeting in June, will assume their posts. They are: Dr. E. C. Texter, Detroit, President; Dr. Stanley Truman, Oakland, Calif., President-Elect; and Dr. U. R. Bryner, Salt Lake City, Treasurer.

The AAGP is now publishing its own regular Journal, *General Practice News,* a four-page bulletin which appears each month. Doing an excellent job in presenting news of interest to men in general medicine is Mr. Mac F. Cahal, who is also Executive Secretary and General Counsel, with offices in Kansas City, Missouri.

Here in Minnesota, where a national movement to improve standards and advance the position of general practitioners began, a Chapter of AAGP has been organized. Last June following a vote to amalgamate the original organization—American College of Physicians and Surgeons—with the newer group, a charter was granted by the AAGP and the Minnesota Chapter, American Academy of General Practice, was launched. It is planned to have regional groups of the organization throughout the state, eight of which are already in existence.

The local chapter is now extending an invitation for general practitioners to join the Academy. Any general practitioner may write for information to Dr. G. P. Wenzel, Secretary of the Minnesota Chapter, 891 Rice Street, St. Paul. It is necessary to become a member of the Minnesota Chapter before one can join the national organization.

Officers of the state group, elected last October, in addition to Dr. Wenzel, are: Dr. C. S. Don-

aldson, Foley, President, and Drs. James Cosgriff, Olivia, C. J. T. Lund, Fergus Falls, and Gordon Samuelson, Mankato, first, second and third Vice-Presidents, respectively.

The purpose of the state organization closely parallels that of the national group and consists mainly in constantly striving to improve the standards of medicine as practiced by the general practitioner. This is to be done by promoting and maintaining high standards of general medicine and surgery, by assisting in providing general practitioners with postgraduate courses and encouraging them to participate in the courses.

PRACTICAL NURSE LICENSURE IN OPERATION ONE YEAR

In operation one year on August 1, 1948, the Minnesota program to examine and license practical nurses promises to aid greatly in filling the need for qualified persons to provide bedside nursing care.

During the year the original Board of Nursing Examiners consisting of seven members has carried out the terms of the Practical Nurse Licensure law, with the assistance of three additional members, one a physician, one a hospital administrator and one a licensed practical nurse.

The Board reports that out of a total number of 461 candidates taking the first examination given on February 21, 424 were passed and were granted L.P.N. degrees.

In the board's major undertaking the past year, it reports that in developing and planning for maintenance of standards for schools of practical nursing, it aimed to prepare a guide to those institutions and organizations planning to conduct accredited schools of practical nursing and for the use of the board as the accrediting body in determining the eligibility of schools for accreditation, the guide to include the purposes and objectives of a school of practical nursing.

Miss Leila Halverson, who has for many years served the Nursing board as its secretary-treasurer and who has most efficiently administered the work of the board, has resigned, effective September, 1948. Miss Helen G. Schwarz becomes the board's executive secretary and will be assisted by Miss Leonora Collatz. Both of these women are extremely well qualified and will continue to carry on the important work of maintaining the standards of nursing in this state.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Julian F. DuBois, Secretary

Minneapolis Painter and Decorator Pleads Guilty to Abortion

Re State of Minnesota vs. Gerald E. Humphries

On September 21, 1948, Gerald E. Humphries, forty-one years of age, 2015 22nd Avenue South, Minneapolis, was sentenced by the Hon. E. A. Montgomery, Judge of the District Court of Hennepin County, to a term of not to exceed two years at hard labor in the State Prison at Stillwater, following Humphries' plea of guilty on September 4, 1948, to an information charging him with the crime of abortion. The Court stayed the sentence and placed the defendant on probation for two years.

Humphries, who is married and the father of four children, was arrested on September 2, 1948, following a report to the Minnesota State Board of Medical Examiners from a Minneapolis hospital, that a twenty-three-year-old Minneapolis woman had been received at the hospital suffering from the after effects of a criminal abortion. The patient stated that she had been aborted on August 19, 1948, by a man she knew only as "Doc." Subsequent investigation by a representative of the Minnesota State Board of Medical Examiners and Minneapolis police officers disclosed that the abortion had been performed by the defendant, Gerald E. Humphries. Humphries was promptly arrested and admitted that he had performed the operation and had received $125 for his services. The defendant also admitted that he had performed a total of seven abortions during the past four years.

The defendant admitted that he had no license to practice any form of healing in the State of Minnesota. He gave his occupation as that of a painter and decorator. He claimed, however, he had been a premedical student for a period of two years.

Minneapolis Pair Plead Guilty Following Arrest for Abortion

Re State of Minnesota vs. Lucille P. Olson and Charles R. Conry.

On September 14, 1948, Charles R. Conry, thirty-two years of age, 3608 Orchard Avenue, Robbinsdale, Minnesota, was sentenced by the Hon. Paul S. Carroll, Judge of the District Court, of Hennepin County, to a term not to exceed four years in the State Prison at Stillwater, following Conry's plea of guilty on July 17, 1948, to an information charging him with the crime of abortion. The Court placed Conry on probation for five years on condition that he remain in the State of Minnesota, be gainfully employed and support his family.

A complaint was issued for Conry and the defendant, Lucille P. Olson, charging each with the crime of abortion. The alleged abortion was performed on a twenty-six-year-old divorced Minneapolis woman who claimed that Conry was responsible for her pregnancy. The defendants were arraigned in the Municipal Court in Minneapolis on June 9, where each waived a preliminary hearing and were held to the District Court for trial. Upon being arraigned in the District Court on the same date, both defendants entered pleas of not guilty,

MINNESOTA STATE MEDICAL ASSOCIATION

House of Delegates

Summary of Proceedings*

Minneapolis Session—June 6-7, 1948

First Meeting, Sunday, June 6, 1948

Gold Room, Hotel Radisson
Minneapolis, Minnesota

The Ninety-fifth Annual Session of the House of Delegates of the Minnesota State Medical Association convened in the Gold Room, Hotel Radisson, Minneapolis, Minnesota, at 2 p.m., Dr. C. G. Sheppard, Hutchinson, Speaker, presiding.

Dr. Sheppard called the meeting to order and asked for the report of the Credentials Committee. Dr. C. S. Donaldson, Foley, reported that a quorum was present. After approval of the minutes of the 1947 session of the House, Dr. Coventry introduced two distinguished guests to the assembly, Dr. L. W. Larson, Bismarck, Secretary of the North Dakota State Medical Association, and Mr. C. H. Crownhart, Madison, Secretary of the State Medical Society of Wisconsin. Both guests addressed the House briefly and brought greetings from their respective organizations. Dr. Sheppard then called on Dr. A. W. Adson of Rochester, who presented a special citation to Dr. Ludwig L. Sogge of Windom.

DR. ADSON: Too often in the course of our normal activities in state societies we give responsibilities to men, expect them to continue and achieve everything that we hold desirable, feeling free to criticize occasionally if they do not come up to our expectations. But when one of our faithful becomes ill, we rush him flowers; and if a demise occurs, we stand around and talk about what a wonderful man he was.

I am very happy to say that the Council through the virtue of its authority from the House of Delegates has seen fit to render a citation to a man who has done noble service, who has arrived at an age when he should be assisted, where we can still use his counsel, but when a younger man should bear the burden.

This citation has been prepared and designed to express our appreciation to Dr. L. L. Sogge, who has for so many years contributed in so many ways to our Association. I would like to read it now.

Be it known by virtue of the authority vested in the Council of the Minnesota State Medical Association by its House of Delegates that this citation is hereby awarded to you, Dr. Ludwig L. Sogge, in recognition of your service to your colleagues and to the people of this state in supplying advice and leadership in maintaining the high standards of medicine. It is known that you, at personal sacrifice, have given much of your time during the past twenty-three years in directing the activities of the Committee on Public Policy. The years of service entitle you to some relief of that responsibility and to the honorable position of counselor to the Committee on Public Policy. Doctor Sogge, we all commend you for this extraordinary service that you have given, which has been exemplified by your high ideals, your understanding of human nature, your honest, frugality, loyalty and patience.

The citation is signed by F. J. Elias, M.D., Chairman of the Council; A. E. Cardle, M.D., President; and B. B. Souster, M.D., secretary.

I hereby take pleasure in presenting this citation to you, Dr. Sogge. *(Applause.)*

At the request of Dr. Sheppard, the House arose and applauded Dr. Sogge.

Dr. Sheppard then asked Dr. F. J. Elias, Duluth, for the report of the Chairman of the Council.

Report of the Council

DR. ELIAS: The first meeting of the Council in connection with the Ninety-fifth Annual Meeting of the Minnesota State Medical Association was held at 2 p.m. on Saturday, June 5, 1948, for the transaction of routine business. Minutes of the previous meetings were approved and financial reports were submitted and accepted.

An opinion from Mr. G. S. Schuster, investment counselor for the Association, was read by the Finance Committee Chairman, which stated that an analysis of the audit of the Minnesota State Medical Association investment portfolio revealed its present position to be conservative.

The President of the Minnesota Heart Association appeared before the Council and presented a proposal to place plastic hearts in physicians' offices during the month of February as a method of collecting funds to promote the Association's objectives: dissemination of knowledge to the profession and laity concerning heart disease; stimulation of research in cardiovascular disease and development of postgraduate medical education courses. The proposal was referred to the House of Delegates.

The Chairman of the Insurance Liaison Committee introduced a proposed brochure which the Committee had developed in conferences with a representative committee from commercial insurance carriers operating in Minnesota. The Chairman of the Committee was instructed to revise the brochure, confining it to a statement of minimum standards which medical insurance contracts sold by insurance companies must meet to receive the approval of the Committee and that all reference to the Minnesota State Medical Association be deleted except insofar as is necessary to refer to the Insurance Liaison Committee as a Committee of the Association which is co-operating in a program to raise the standards of benefits of prepayment medical insurance contracts sold in Minnesota.

Applications for Affiliate Membership were approved for Dr. Margaret I. Smith, Robbinsdale; Dr. Peter Boysen, formerly of Pelican Rapids; and Dr. P. H. Benion, Saint Paul. Life Memberships were approved for Dr. Clarence W. Taylor of Duluth and Dr. O. H. Hegge of Austin.

The Council adjourned for dinner at 5:45 p.m. and re-convened in the Spanish Room at 7 p.m. for the completion of routine business.

*In accordance with action by the Council of the Minnesota State Medical Association in 1944, publication of the proceedings of the House of Delegates is limited to summary.

A resolution from the Chairman of a special committee to study the question of rebates was introduced.

A committee was appointed to study the question of the State Association's interpretation of the term "clinic" in connection with group practice and to confer with the American Medical Association and the Council on Economic Research, both of which are working on definitions of the term, and report back to the Council.

The appointment of Dr. Charles E. Proshek of Minneapolis to succeed Dr. T. H. Sweetser, who has resigned as the Chairman of the Committee on State Health Relations, was approved.

The appointment of Dr. Theodore Catlin of Buffalo and Dr. Frederick L. Schade of Worthington on the Advisory Board to the Minnesota Department of Health under the hospital licensing law, was approved by the Council. Dr. Thomas E. Broadie of St. Paul was approved for reappointment on the Advisory Board to the Health Department under the hospital superintendent registration law.

A report was introduced from the Sub-Committee appointed by the Committee on Tuberculosis to draft a statement concerning the use of BCG as set forth in the minutes of the meeting of the Tuberculosis Committee, held February 6, 1948, for referral to the proper Reference Committee, whereupon the Council recommended its referral to the Reference Committee on Officers and Council Reports. The meeting of the Council was adjourned at 9:30 p.m.

The second meeting of the Council in connection with the Ninety-fifth Annual Session was held at 9 a.m., Sunday, June 6.

The Chairman of the Committee on Cancer appeared before the Council and outlined a project proposed by the Committee in conjunction with the Cancer Control Division of the Minnesota Department of Health to provide a Cancer Education Service, co-sponsored by the Cancer Committee, Minnesota State Medical Association; Medical School, University of Minnesota, the Health Department and the Minnesota Division of the American Cancer Society.

The project is described as follows:

A PROJECT TO BE KNOWN AS THE CANCER EDUCATIONAL SERVICE OF THE CANCER COMMITTEE OF THE MINNESOTA STATE MEDICAL ASSOCIATION

Purpose—To establish a Cancer Educational Service which would be readily available to Minnesota county medical societies, hospital staffs and individual physicians.

Consultants—A group of recognized specialists who are qualified to give authoritative opinion on some phase of cancer diagnosis or treatment, selected by the Cancer Committee from volunteers. this group may be added to at any time to include physicians for special problems.

Plans—The Cancer Educational Service will offer three types of service without expense to local physician, hospital staff or county society.

(a) A team of from three to five members of the Cancer Educational Service will be offered to any component society of the Minnesota State Medical Association for a one-day cancer institute.

(b) One or possibly two members of the Cancer Educational Service will be available to meet with any hospital staff in the state, no matter how small, for an afternoon or evening cancer discussion.

(c) A free cancer correspondence service for physicians wishing information regarding any problem in a specific cancer case. Inquiries will be referred to a member of the Cancer Educational Service who seems best qualified to answer. Names of physicians making the inquiry will not be divulged and the opinion of the cancer consultant will be forwarded to the inquiring physician. Inquiries of special interest and the consultant's opinion will be published in MINNESOTA MEDICINE from time to time, without using names of physician or consultant.

Headquarters—The office of the Minnesota State Medical Association shall be the headquarters of the Cancer Educational Service of the Cancer Committee.

Operation—The Cancer Educational Service will be carried on under the direction of the Cancer Committee of the State Medical Association. All communications relative to this service shall be mailed out on special stationery of the Minnesota State Medical Association Cancer Committee, carrying the address of the State Medical Association headquarters in St. Paul. The Cancer Control Division of the Minnesota Department of Health will finance a secretarial service to aid in the operation of the Educational Service. This secretarial service will take care of scheduling the consultants for county medical society and hospital staff meetings. Also this service will submit correspondence inquiries to the selected consultant and transmit the reply to the inquiring physician. The Cancer Control Division of the Minnesota Department of Health will aid the Cancer Committee in every way in promoting and carrying out these institutes and staff meeting conferences.

Financing—This service will be principally financed through funds of the Cancer Control Division of the Minnesota Department of Health, but other organizations, such as the Minnesota Division of the American Cancer Society may also contribute to this service. Consultants will be paid an agreed stipend for the services rendered.

* * *

The Council approved this project subject to the declared principles that clinical material shall be used solely for educational purposes and the recommendation that the use of cancer teams be arranged through officials of component medical societies only.

A letter of resignation addressed to the Council by Dr. A. W. Adson as a member of the American Medical Association House of Delegates from Minnesota was read and accepted.

The Council approved a motion to place in nomination the name of Dr. J. A. Bargen, Rochester, as a nominee for membership in the AMA House of Delegates from Minnesota at the expiration of Dr. Adson's present term.

The Council recommended the nomination of Dr. W. A. Coventry to succeed himself as a member of the AMA House of Delegates from Minnesota.

The nominations of Dr. W. L. Burnap, Fergus Falls, and Dr. J. C. Hultkrans, Minneapolis, to succeed themselves as alternate members of the AMA House of Delegates from Minnesota were approved by the Council.

The Council voted to endorse unanimously the candidacy of Dr. A. W. Adson of Rochester for the office of President-Elect of the American Medical Association. *(Applause.)*

* * *

With the recommendation that the question of the resolution on rebates presented in the Council report be laid on the table for further action, the House of Delegates approved the report of the Chairman of the Council.

Speaker Sheppard then called for the report of the Finance Committee from Dr. R. L. J. Kennedy, Rochester, Chairman.

Report of the Finance Committee

DR. KENNEDY: The wisdom and good judgment of the preceding Finance Committee continues to be confirmed by the present financial condition of the Minnesota State Medical Association. Although it appears to be satisfactory, there is evidence that the Association is operating on a narrower financial margin in respect to income and expenses than it has during recent years. The increase of income from dues from an increased membership has been more than offset by mounting costs of supplies and of help, by additional expenses due to increased activities of various committees and by decreased income from the annual meetings, due to increased costs of installation of exhibits.

The investment portfolio of the Association has undergone little change. The conservative policy that has been followed in the past continues to be reliable. The advice of experts in the field of investment is to maintain the portfolio as it has existed for the past two years.

Financial conditions during the past year have again emphasized the importance of maintaining a strong reserve position. In the opinion of the members of the

Finance Committee, the investment fund of the Association is not large and with world affairs as unsettled as they are at present, weakening of the reserve position should be avoided.

The State Medical Association continued the financing of the Veterans Medical Service Division during the year 1947. Anticipating the financial relationship of the State Medical Association to the Veterans Medical Service Division for the year 1948, it may be stated that the repayment of funds advanced to the Veterans Medical Service Division has already begun.

During the past year the Association implemented a group insurance plan which was developed by the Northwestern National Life Insurance Company for the active members of the State Medical Association. The State Medical Association will be reimbursed for expenses that were incurred at the end of the year 1948. For various reasons all of the component societies did not qualify for participation by their members in this insurance program. In the opinion of the members of the Finance Committee, the insurance program is highly desirable, and it is hoped that by the time of the next annual insurance date the rest of the component societies will have qualified for participation and that the insurance company will make it possible for the members of such component societies to enjoy the benefits of this program.

The Finance Committee wishes to acknowledge indebtedness to the Executive Secretary of the Association and to his staff for the aid received throughout the year and the help in preparation of reports on the financial status of the State Medical Association.

The members of the Finance Committee in addition to the Chairman are: Frank J. Elias, M.D., Ernest M. Hammes, M.D., A. E. Cardle, M.D., *ex officio.*

* * *

The House of Delegates accepted the report of the Finance Committee, as presented.

The Delegates next heard a comprehensive report of the findings of a special committee, appointed at the 1947 meeting of the House, to investigate insurance contracts, disability features and group life insurance. Presenting the report was Dr. Thurston W. Weum, Minneapolis, Chairman. The report was accepted by the House.

Reports of Reference Committees

The next order of business was the reports of the various reference committees. The Speaker called first upon Dr. H. M. Carryer, Rochester, Chairman of the Reference Committee on Medical Education Reports.

Medical Education Reports

Dr. Carryer: Your Reference Committee on Medical Education Reports met at 10 a.m. June 6, 1948. The following Medical Education Reports were considered:

Committee on Cancer—A. H. Wells, M.D., Duluth, Chairman

Committee on First Aid and Red Cross—J. S. Lundy, M.D., Rochester, Chairman.

Heart Committee—F. J. Hirschboeck, M.D., Duluth, Chairman

Committee on Hospitals and Medical Education—H. S. Diehl, M.D., Minneapolis, Chairman

Committee on Public Health Nursing—Mario McC. Fischer, M.D., Duluth, Chairman

Committee on Syphilis and Social Diseases—Paul A. O'Leary, M.D., Rochester, Chairman

Committee on Tuberculosis—J. A. Myers, M.D., Minneapolis, Chairman

Committee on Vaccination and Immunization—Robert N. Barr, St. Paul, Chairman

Certain items concerning these reports were considered worthy of comment. The Reference Committee on Medical Education Reports was pleased to note the report of the Committee on Hospitals and Medical Education which was submitted by Dr. Diehl. It was especially significant in that those primarily concerned with the training of medical students have emphasized an indoctrination for the general practice of medicine. A policy of providing "general practice internships" will better equip a medical student for the general practice of medicine, and will also provide a more adequate foundation for those wishing training in the various medical specialties. It was felt that the quality of medicine, as it is practiced in the state of Minnesota can only be enhanced by the trend now evident in medical teaching in this state.

The Committee on Medical Education Reports is impressed by the splendid record of achievement of these several committees, the reports of which were reviewed at this meeting. I move the adoption of these reports.

* * *

After some discussion, the House voted to adopt the report of the Reference Committee on Medical Education Reports. Dr. Sheppard called next for the report of the Reference Committee on Miscellaneous Scientific Reports, Dr. J. F. Borg, St. Paul, Chairman.

Miscellaneous Scientific Report

Dr. Borg: Your Committee has carefully considered the following reports:

Committee on Anesthesiology—R. C. Adams, M.D., Rochester, Chairman

Committee on Child Health—G. B. Logan, M.D., Rochester, Chairman

Committee on Diabetes, J. R. Meade, M.D., St. Paul, Chairman

Committee on Fractures—E. T. Evans, M.D., Minneapolis, Chairman

Committee on General Practice—R. H. Creighton, M.D., Minneapolis, Chairman

Historical Committee—M. C. Piper, M.D., Rochester, Chairman

Committee on Industrial Health—L. S. Arling, M.D., Minneapolis, Chairman

Committee on Maternal Health—J. J. Swendson, M.D., St. Paul, Chairman

Committee on Medical Testimony—E. M. Hammes, M.D., St. Paul, Chairman

Committee on Military Affairs—J. H. Tillisch, M.D., Rochester, Chairman

Committee on Nervous and Mental Diseases—W. P. Gardner, M.D., St. Paul, Chairman

Committee on Ophthalmology—T. R. Fritsche, M.D., New Ulm, Chairman

Committee on Public Health Education—S. H. Baxter, M.D., Minneapolis, Chairman

Radio Committee—R. M. Burns, M.D., St. Paul, Chairman

Speakers' Bureau—F. J. Heck, M.D., Rochester, Chairman

Your Committee approved the above reports with the following qualifications:

Your Committee approves the report of the Committee on Anesthesiology, but recommends that it communicate with the Committee on Anesthesiology and state that it is suggested that it be the recommendation of the House of Delegates that it include in its program and its aims the encouragement of the training of nurses for anesthesia administration in such locations as it is necessary to use them. This Committee suggests that the Committee on Anesthesiology also encourage the inclusion of proper training in anesthesia of all students in the curriculum of the Medical School of the University of Minnesota.

Your Committee accepts the report of the Historical

Committee and recommends that the Council take favorable action on the suggestion that the material prepared to date be published. It is also recommended that Dr. Piper be given opportunity to express before the House of Delegates in connection with the submission of this report developments concerning this project.

Your Committee recommends the acceptance of the recommendations of the Committee on General Practice exclusive of paragraphs two and five, which are debatable, and it is suggested that these paragraphs be brought before the House of Delegates for discussion. It is also suggested that these recommendations be transmitted to the Dean of the Medical School as representative of the consensus of the Committee on General Practice.

Your Committee respectfully moves the approval of these reports.

Dr. Piper was then called upon to elaborate on the discussion of the proposal to publish the material on medical history in Minnesota. Following his discussion, it was moved that the House of Delegates authorize the Council to proceed to work out arrangements for the publication of the first volume of the History of Medicine in Minnesota, that the Historical Committee should have the assistance of the Editing and Publishing Committee in editing the material and that the Executive Secretary be empowered to inquire of the State Medical Association whether they will subscribe to the pre-publication subscriptions to the volume. The motion was carried.

Dr. Jan H. Tillisch, Chairman of the Committee on Military Affairs, then outlined for the delegates the work of the AMA Council on National Emergency Medical Service, which is laying groundwork for a program to be set in motion in the event of another national emergency. He described nationwide activities in setting up state disaster committees and explained how the government is preparing for defense with the setting up of the National Resources Board which will control material and personnel for the military and for civilians if and when there is another war.

Dr. Tillisch told the delegates that in the event of war, or in connection with national defense plans, reserve officers of both the navy and army medical corps may be called in at any time at the discretion of the President and that inactive members of the naval reserve probably will not be called in without official permission of Congress.

Dr. Ralph H. Creighton, Chairman of the Committee on General Practice appeared before the House to explain and comment on the two paragraphs in question from the report submitted by his committee. Following the discussion over the two points: paragraph 2 suggesting that candidates for specialty training take preliminary training in general practice and paragraph 5 making it essential that hospitals establish rotating internships with integrated teaching programs before being granted AMA approval, the House voted to accept the Report of the Reference Committee on Miscellaneous Scientific Reports, with paragraphs 2 and 5 deleted and paragraph 5 to be referred to the Committee on Medical Education and Hospitals.

Officers' and Councilors' Reports

Dr. C. W. Moberg, Detroit Lakes, Chairman of the Reference Committee on Officers' and Councilors' Reports, was called upon next.

Dr. Moberg: Your Committee has considered the reports of the Officers and Councilors very carefully and has found them to be complete. . . . I would now like to take up each report considered and make a few comments.

As regards the report of the Secretary and Executive Secretary, your Committee was impressed with the volume of work that now flows through the state office. The report was excellent and complete. We recommend the acceptance of the report.

Next to be considered was the report of our Treasurer, Dr. W. H. Condit. We recommend that this report also be accepted. The report of the Chairman of the Council was very elaborate and complete. It contained several important matters meriting special consideration by the House.

The first matter we should like to call to the special attention of the Delegates is the recommendation that the matter of Rh typing be reconsidered. . . .

The next matter warranting . . . the special attention of the House is a recommendation made jointly by the Committee on Military Affairs and the Committee on First Aid and Red Cross, which was presented to the Council and is reported by the Council Chairman and referred to the House for action. These two Committees wish to be combined and become known as the Committee on Emergency Medical Service. Your Reference Committee requests that the House of Delegates consider this matter.

On specific referral to your Reference Committee by the Council at its meeting last night, the matter of BCG and its use in Minnesota was discussed in connection with the Chairman of the Council's report. (Dr. Moberg read a paragraph from the report of the Committee on Tuberculosis, which was being presented by the Committee as a substitute for the resolution passed by the 1947 House in regard to BCG.)

An important matter discussed in the Council report is that of publication of the minutes of the Council—in edited form—in Minnesota Medicine. We urge that the House consider this proposal pro and con. . . .

A final consideration in the Council Chairman's report, which the Reference Committee would like to direct to your attention, is discussed in the last three paragraphs. It is evident from this report that the activities of organized medicine in this state are rapidly expanding and that there is a great need for such expansion in view of the importance of maintaining an active public health and public service program by the state association. These increased activities place a burden upon the state office staff which is rapidly approaching a serious problem. It calls for some action from the House of Delegates as a whole to assume more of the responsibility. As suggested in the Council report, it might be wise to procure a competent assistant secretary to assume a fair share of the public relations work and to relieve the burden of some of the multiple details falling upon the state office at the present time.

In view of these considerations, your Committee respectfully recommends that sufficient assistance shall be provided for our state office to carry out its many activities and to secure additional personnel as needed to conduct these activities efficiently.

We further recommend that our annual dues be increased if needed to provide for the additional personnel. The amount of increase in dues should be a joint responsibility of the Finance Committee and the Council.

With these recommendations we have accepted the report of the Chairman of the Council and we move its adoption by the House.

Your Reference Committee has considered carefully each of the reports of the Councilors. We are of the opinion that many of the problems cited are local in nature and should be handled by the individual districts. But before recommending action on these reports, we should like to call attention to a couple of details. The first is that of the importance of ALL LOCAL SOCIETIES notifying the District Councilor of ALL MEETINGS so that he may have an opportunity to be present. Thus, there can be maintained the closest possible contact between the Council and the component county medical societies within the Association.

The Councilor of the Fifth District reports that since there are only five county members in the Dakota County Medical Society and that most of the members in that attend meetings with Ramsey or Hennepin or Goodhue Counties, and some have joined nearby societies, that the Dakota County Medical Society be permitted to dissolve should it desire to do so in order that its members may officially join the medical society which is nearest and most convenient for them.

Your Committee now wishes to recommend the adoption of the Councilor reports, and I so move. This includes the following reports:

First District—R. L. J. Kennedy, M.D., Rochester
Second District—L. L. Sogge, M.D., Windom
Third District—L. G. Smith, M.D., Montevideo
Fourth District—A. E. Sohmer, M.D., Mankato
Fifth District—E. M. Hammes, M.D., St. Paul
Sixth District—O. J. Campbell, M.D., Minneapolis
Seventh District—W. W. Will, M.D., Bertha
Eighth District—W. L. Burnap, M.D., Fergus Falls
Ninth District—F. J. Elias, M.D., Duluth

Dr. Sheppard, following a motion to accept the Report of the Reference Committee on Officers' and Councilors' Reports, opened the report for discussion. The first to address the House was Dr. Kano Ikeda, St. Paul, speaking for the Minnesota Society of Clinical Pathologists and other pathologists of the state. He asked that the resolution passed by the 1947 House of Delegates that the State Department of Health be required to do Rh typing be rescinded. After a lengthy discussion, the House voted to rescind its previous action.

The next item to be considered was Dr. H. C. Hinshaw's report as to accepting his statement on BCG in lieu of a resolution passed by the House in 1947. Following a brief discussion, the statement prepared by Dr. Hinshaw was referred back to the Reference Committee on Medical Education Reports for further consideration. The Committee was requested to report back to the House following its discussion of the statement on BCG.

It was next ordered by the House that the matter of increase of dues should be further studied.

The next matter to be considered was the merging of the Committees on Military Affairs and First Aid and Red Cross into one committee to be known as the Committee on Emergency Medical Service. The motion to combine these two committees was lost.

The meeting of the House was recessed at 5:40 p.m.

Second Meeting, Sunday, June 6, 1948

Gold Room, Hotel Radisson
Minneapolis, Minnesota

The House of Delegates reconvened at 8 p.m. The first person to address the House was Dr. William F. Braasch, Rochester, who introduced to the Delegates Mr. Harold E. Stassen, former Governor of Minnesota, and candidate for the Presidency of the United States.

Mr. Stassen addressed the House in regard to his candidacy, stating his position with regard to health and government in America. He thanked the medical profession for its support of his candidacy, reviewed some of the work which he had carried on with the physicians of the state during the period while he was governor and pledged that in the event he should be elected president, he would never permit a law to become an act with his signature which affects medicine or health that is not approved by the American medical profession.

Following Mr. Stassen's address, the Credentials Committee reported that a quorum was present.

The next item of business was a report from Mr. Jarle Leirfallom, director of the Division of Social Welfare.

Mr. Leirfallom expressed appreciation of the Division to the doctors of Minnesota for the services to the indigent during the year. He told of meeting with the Association Medical Service Committee for the purpose of discussing the fee schedule for care of indigents. He said that he was impressed with the thoughtful and co-operative attitude of the Committee and he reported that the increase in fees was acceptable to the Division which is cognizant of the need for such an increase.

He urged the activation of all medical advisory committees throughout the state since they are of immense value to the Division in its work. He discussed briefly the program for service to crippled children and reported that it is felt generally that the program is a successful one.

Mr. Leirfallom expressed regret over the loss of the services of Dr. Edwin J. Simons, who resigned as chief of the medical services unit during the year. He said that the Division was very fortunate in securing Dr. F. F. Callahan for that post and that Dr. Callahan was doing an excellent job.

Dr. A. W. Adson, Rochester, Chairman of the Medical Service Committee which was responsible for negotiating with the Division of Social Welfare in the matter of fees for care of indigents, spoke briefly regarding the proposed upward revision of fees. He also emphasized the need for county medical advisory committees.

Dr. Sheppard then called upon Dr. O. I. Sohlberg, St. Paul, who reported on the activities of Minnesota Medical Service, Incorporated, of which he is President. Dr. Sohlberg said that Minnesota Medical Service was incorporated on January 10, 1947, and that its By-Laws, adopted, February 1, 1947, were approved by the Attorney General on April 27, 1947. The plan, now known as "Blue Shield," Dr. Sohlberg said, began enrolling subscribers on November 15, 1947, although official inauguration ceremonies were not held until April 12, 1948. At the ceremonies, held at Northrop Memorial Auditorium on the campus of the University of Minnesota, Dr. Paul R. Hawley, formerly of the Veterans Administration and now head of the national Blue Shield-Blue Cross Commission, was the principal speaker. Attending were some 800 doctors, civic leaders and government officials, Dr. Sohlberg reported.

As of May 1, Dr. Sohlberg said, a total of 2,101 doctors were enrolled as participants and over 21,000 persons were covered. The financial condition of Blue Shield, he said, is healthy; and he expressed the belief that it would continue to prosper.

A brief question-and-answer period followed, at which Dr. Sohlberg and Mr. Arthur M. Calvin, director of Blue Cross and acting director of Minnesota Medical Service, Incorporated, answered questions from the floor of the House.

Next to be heard was the report of the Minnesota State Board of Examiners in the Basic Sciences, given by Dr. Raymond N. Bieter, Minneapolis, Secretary-Treasurer. Following Dr. Bieter's report, Dr. Julian F. DuBois, Secretary, Minnesota State Board of Medical Examiners, presented a report of the Board's activities.

Dr. J. I. Fitzsimmons, Assistant Medical Director, Veterans Administration Branch Office No. 8, Fort Snelling, addressed the delegates briefly regarding the medical phases of the VA program. He reported that the Veterans Medical Service program, known as the Home-Town Medical Care program, which has been functioning for a year and a half, has proved satisfactory to the Veterans Administration. He thanked the medical profession for its assistance in the past and expressed the hope that it will continue to assist the Veterans Administration in the future.

Major Arthur Tarrow, Professor of Military Science and Tactics, University of Minnesota, spoke to the Delegates in regard to a program which the army has inaugurated to increase the number of physicians to care for an augmented peace-time army.

Next to be presented was the report of the Minnesota Hospital Construction and Planning Program, given by Dr. Helen L. Knudsen, Director.

Dr. Knudsen reported that Minnesota became eligible for federal aid in the construction of a number of hospitals with the approval of the Minnesota Plan on March 5, 1948. The State Board of Health is responsible for planning and construction phases of the program, she said.

According to present plans, Dr. Knudsen said, the completion of the Minnesota hospital building program will bring the majority of the population within an approximate radius of 20 miles of a hospital. Dr. Knudsen also outlined plans regarding mental disease hospitals, tuberculosis hospitals, chronic disease hospitals and public health centers.

The Hospital Survey and Construction Act authorizes an annual grant of $1,655,175 over a five-year period to assist in building needed hospitals and public health centers in Minnesota, according to Dr. Knudsen. Plans are to use the first year's funds mainly for general hospitals, with one institution being built in each of the public health center and chronic disease hospital categories. Federal funds constitute one-third of the total cost of the program, Dr. Knudsen said.

A brief report from Dr. A. J. Chesley, Secretary and Executive Officer of the State Department of Health, followed Dr. Knudsen's talk.

A report from the University of Minnesota Medical School was then presented by Dr. M. M. Weaver, Assistant Dean, after which Dr. George N. Aagaard, recently appointed Director of Postgraduate Medical Education, was presented to the Delegates.

Dr. William F. Braasch, Rochester, a member of the Board of Trustees of the American Medical Association, told the Delegates about some of the work being done by the Board and the problems facing the Board, covering the extension of prepayment medical care plans, participation in the National Health Assembly, and the mid-winter meeting of the AMA House of Delegates to be held in St. Louis.

The discussion of the report of the Reference Committee on Officers' and Councilors' Reports was then resumed by the House. Dr. Sheppard opened the discussion on the matter of publication of edited reports of Council proceedings in Minnesota Medicine.

A motion to mimeograph the edited Council reports and distribute them to the Secretaries of the component medical societies was passed by the Delegates in lieu of publication of these proceedings in Minnesota Medicine.

Dr. Elias presented a report of a meeting of the Council, held following the afternoon meeting of the House of Delegates, at which the question of dues and rebates were discussed. Dr. Elias reported as to regulations in the Constitution regarding the fixing of Association dues, which require that "the annual dues shall be determined by the House of Delegates, but shall not exceed the sum of twenty dollars per capita per annum except on a two-thirds vote of the Delegates present." It was suggested at the Council meeting, Dr. Elias reported, that this portion of the Constitution be amended to read "thirty dollars." However, the Constitution, it was reported, prescribes the manner of amendment so as to require the publication of the proposed amendment and the submission of the proposed amendment to the membership not less than three months prior to the House of Delegates meeting at which action is to be taken.

Lack of a quorum prohibited further action. The House of Delegates recessed at 10:55 p.m. to reconvene the following day at 12:15 p.m.

Third Meeting, Monday, June 7, 1948

Gold Room, Hotel Radisson
Minneapolis, Minnesota

Following a luncheon at 12:15 p.m., the House of Delegates reconvened at 1:30 p.m. with Dr. Sheppard presiding. Dr. Donaldson reported that a quorum was present.

The first item of business was the resumption of the Officers' and Councilors' reports, with a report from Dr. Haddon M. Carryer's Reference Committee on Medical Education Reports to which was referred the question of BCG. Dr. Carryer presented the following resolution on BCG:

Whereas it is a well known clinical fact that tuberculosis is a disease against which the human body frequently cannot develop strong, dependable and permanent immunity and

WHEREAS the use of BCG vaccine is authoritatively reported to provide a relative immunity of varying degree and duration, and

WHEREAS the American Trudeau Society, after extensive consideration, has said "BCG vaccine, prepared under ideal conditions and administered to tuberculin negative persons by approved techniques, can be considered harmless," be it therefore

RESOLVED that the House of Delegates of the Minnesota State Medical Association approve the use of BCG vaccine in the state of Minnesota,

1. PROVIDED that its use be limited to those persons with negative tuberculin skin test reactions who may be exposed to unusual hazards of tuberculous infection greater than the danger experienced by the general population, and
2. PROVIDED that vaccination be carried out under conditions which permit prolonged observation of all vaccinated persons and
3. PROVIDED that the vaccine employed be obtained from the laboratories approved by the United States Public Health Service or the Minnesota State Board of Health, and
4. PROVIDED that all instances of persons vaccinated with BCG shall be reported to the Minnesota State Board of Health, and
5. PROVIDED that recognition be given to the fact that the use of BCG vaccine is not a substitute for accepted methods of tuberculosis prevention and control, and should not lead to a relaxation of such precautions.

The House of Delegates voted to accept this resolution in lieu of the resolution on BCG passed by the 1947 House.

Dr. Carryer reported that his Committee had studied the question of the advisability of placing plastic hearts in physicians offices during the month of February, a matter previously referred by the House to the Committee on Medical Education Reports, and had concluded that the plan could be adopted, provided it was carried out with the approval of the county medical society and the individual physician in whose office the funds are to be solicited. The House voted to approve the plan.

Dr. Elias then presented the matter of dues and reported further action by the Council on the matter. Dr. Elias reported that in view of the necessity of publication and notification three months in advance of any action to be taken with regard to amending the Constitution, the Council wished to recommend that a special assessment of ten dollars be allowed, commencing the first of next year, January, 1949. Dr. Elias stated that this should take care of the program of increased activities until such time as the Constitution could be properly amended.

The House of Delegates then voted to accept the report of Dr. Elias for the Council, and, at the suggestion of the Chairman of the Finance Committee, a second motion was made and passed accepting the special assessment for 1949 dues. That concluded the material covered in the Report by the Reference Committee on Officers' and Councilors' Reports. A motion was passed by the House accepting the Report.

* * *

Dr. Sheppard called upon Dr. F. W. Behmler of Morris for the report of the Reference Committee on Medical Economics Reports.

Medical Economics Reports

DR. BEHMLER: The Reference Committee on Medical Economics Reports met yesterday with all members present. After studying the report of the Editing and Publishing Committee, approval was given, with a special commendation for the valuable work of Mr. J. R. Bruce as Business Manager and Dr. Carl B. Drake as Editor of MINNESOTA MEDICINE. Mr. Speaker, I move the adoption of the report. (The Delegates voted approval.)

The Reference Committee approves the report of the Committee on Interprofessional Relations without further comment. (House approved the report.)

The Reference Committee approves the report of the Medical Advisory Committee and also commends the Committee on the formation of the Joint Grievance Committee. (House approved report.)

After studying the report of the Committee on Medical Economics, we approve the report and wish to commend the Committee on its continued effort to preserve our present system of medical care. (House approved report.)

The Reference Committee approves the report of the Committee on Medical Ethics with no comment. (House approved report.)

The Reference Committee also approves the report of the Committee on University Relations with no comment. (House approved report.)

The Reference Committee thoroughly considered the report of the Committee on Public Policy. The Committee heartily approves the reorganization of the Committee on Public Policy with the increase in membership. It also gives 100 per cent approval of its five point program. . . .

We believe that a Public Relations Counsel should be obtained either on a full-time or extensive part-time basis. An active program on public relations should be carried out by the Minnesota State Medical Association immediately. . . . We wish to emphasize the need and value of the county health unit bill and urgently recommend a study of this question of county units by a committee of the Council, to be presented to our Public Policy Committee.

Following the acceptance by the House of the report of the Committee on Public Policy, the report of the Reference Committee on Medical Economics Reports was complete. The next item of business was the report of the Reference Committee on Miscellaneous Medical Economics Reports, Dr. F. L. Schade, Worthington, Chairman.

The House accepted the five reports considered by the Committee, with the recommendations as follows:

Insurance Liaison Committee—A. W. Adson, M.D., Rochester, Chairman

Committee on Medical Service—Dr. Adson, Chairman, with the suggestion that a study be made of the optical code used by the State Welfare Board.

Committee on Rural Medical Service—Paul C. Leck, M.D., Austin, Chairman

Committee on State Health Relations—T. H. Sweetser, M.D., Minneapolis, Chairman, with the recommendation that a study be made of the coroner situation, particularly in rural areas of the state.

Committee on Veterans Medical Service—R. H. Creighton, M.D., Minneapolis, Chairman, with the recommendation that the attention be again called to the importance of enrolled physicians' filing and promptly returning all VA forms in connection with treatment rendered veterans.

It was subsequently moved by the House that the Committee on Rural Medical Service should study the township system with regard to the care of indigents with the purpose of finding a better method for providing medical care for these unfortunates, perhaps replacing them with a good county welfare board system.

Next was the report of the Resolutions Committee, Dr. R. R. Cranmer, Minneapolis, Chairman.

DR. CRANMER: WHEREAS the weekly broadcast on health conducted under the auspices of the Minnesota State Medical Association passed its twentieth anniversary on the air this year, and

WHEREAS the Minnesota State Medical Association has been very fortunate in securing the services of Dr. Stewart C. Thomson, Associate Professor of Public Health of the University of Minnesota, as speaker on these broadcasts, and

WHEREAS station WCCO has carried this program without cost to the Association during these many years, now be it therefore

RESOLVED that this House of Delegates express its deep appreciation to Dr. Thomson and to station WCCO for their splendid contributions in making these public health education programs possible.

The thanks and appreciation of the House of Delegates is hereby extended:

To the officers and members of the Hennepin County Medical Society, the Hennepin County Medical Auxiliary and its Committee on Local Arrangements for their services and co-operation in making possible this fine Minneapolis meeting;

To the management of the Hotel Radisson and all of the hotels in Minneapolis for courtesies extended to our guests;

To radio stations WCCO, KSTP, WLOL, WDGY and WCTN, and their staffs, for making possible the fine schedule of broadcasts arranged in connection with the meeting; and

To the Minneapolis *Morning Tribune,* the Minneapolis *Star* and the Saint Paul *Dispatch-Pioneer Press* for their excellent reporting of scientific sessions held in connection with this meeting and for their generous contributions of space to advance announcements.

* * *

RESOLVED that the House of Delegates of the Minnesota State Medical Association commend the renewed interest in, and the increased cognizance of the work which must be done in caring for inmates of the state institutions. It wishes particularly to commend the work being done by the Governor's Advisory Committee on Mental Health and to urge the continuance of this project.

It is requested that if this resolution is adopted that a copy of it be forwarded to the Chairman of the Governor's Advisory Committee on Mental Health.

* * *

RESOLVED that the House of Delegates go on record as supporting the Council on Emergency Medical Service of the American Medical Association in its efforts to secure medical representation on the National Resources Planning Board; and be it further

RESOLVED that this action of the House of Delegates be brought to the attention of the Council on Emergency Medical Service of the American Medical Association and other official bodies as may be necessary to implement this resolution.

* * *

BE IT RESOLVED by the House of Delegates of the Minnesota State Medical Association that the medical faculty of the University of Minnesota be cognizant of the predicament of non-metropolitan areas of the state which lack well-qualified practitioners in Eye, Ear, Nose and Throat. This is the result of the rigid division of training for specialization in either Eye *or* in Ear, Nose and Throat. Minnesota is predominantly a rural state—in area and in population—and the need for these services in the rural areas is becoming more acute.

BE IT FURTHER RESOLVED that the Medical Faculty of the University of Minnesota be urged to investigate this undesirable situation and find means in their training curriculum to rectify it.

The House of Delegates approved all of the above resolutions, thus completing the report of the Resolutions Committee.

Dr. Sheppard then called upon Dr. Elias, Chairman of the Council, for a final report from the Council.

DR. ELIAS: In reporting on the activities of the Council since the session of the House of Delegates last night, your Chairman wishes to state that the members of the Council were guests of the officers and members of the Board of Directors of Minnesota Medical Service at a breakfast meeting at 7:30 this morning. This was the first annual business session of that organization.

(I might add that this was a very fine meeting and that the Council was in agreement with all of the work and proposals that the Service has engaged in up to this time.)

The Council withdrew from that meeting to convene at 10 a.m. for completion of discussions on the resolution regarding the question of rebates. I will now restate the resolution as it now stands for the action of the House of Delegates:

The Council hereby declares itself unalterably opposed to all forms of rebates and declares the acceptance of such as an unethical practice and grounds for disciplinary action by the county societies.

It is recommended that any practice which might give rise to public suspicion that a business arrangement exists between a commercial house and a physician be discontinued.

The Council assures the House of Delegates that it is fully aware of the serious damage to our public relations which has occurred due to the publicity given the government action against the members of our Association.

The Council will stay alert and will inform the county societies when it is timely to implement the above suggested action.

* * *

The House voted its approval of the report of the Chairman of the Council.

The next order of business was the reading of the names of members who died during the past year. Dr. M. C. Piper, Rochester, read the names of 55 physicians, after which a moment of silence was observed.

The next order of business was the election of officers. The following were unanimously elected by the Delegates:

President-Elect: E. M. Hammes, M.D., St. Paul

First Vice President: Charles E. Proshek, M.D., Minneapolis

Second Vice President: A. E. Sohmer, M.D., Mankato

Secretary: B. B. Souster, M.D., St. Paul (re-elected)

Treasurer: W. H. Condit, M.D., Minneapolis, (re-elected)

Speaker of the House: C. G. Sheppard, M.D., Hutchinson, (re-elected)

Vice Speaker of the House: H. M. Carryer, M.D., Rochester, (re-elected)

Councilor, Fourth District: H. J. Nilson, M.D., North Mankato

Councilor, Fifth District (to fill the unexpired term of Dr. Hammes): Justus Ohage, M.D., St. Paul

Councilor, Sixth District: O. J. Campbell, M.D., Minneapolis, (re-elected)

Councilor, Eighth District: W. L. Burnap, M.D., Fergus Falls, (re-elected)

Delegates to the American Medical Association: J. A. Bargen, M.D., Rochester, and W. A. Coventry, M.D., Duluth, (re-elected)

Alternates: J. C. Hultkrans, Minneapolis, (re-elected) and W. L. Burnap, Fergus Falls, (re-elected)

The final order of business was the selection of the meeting place for the 1949 Convention. The House of Delegates voted to accept the invitation from the Ramsey County Medical Society to hold the meeting in Saint Paul.

At 3:07 p.m. the Ninety-fifth Annual Meeting of the House of Delegates was adjourned.

SPECIAL FEATURES

At the annual banquet of the Minnesota State Medical Association, held Tuesday evening, June 8, 1948, at Hotel Radisson, Minneapolis, several Minnesota physicians were given special recognition.

Admitted to the Minnesota State Medical Association's *Fifty Club* were: Drs. Frank E. Burch, J. S. Gilfillan and Asa M. Johnson, St. Paul; Gerhard A. Dahl, Mankato; A. S. Fleming, A. E. Hedback, C. J. Lind, J. R. Peterson and N. H. Sheldrup, Minneapolis; W. F. C. Heise, Winona; J. G. Parsons, Crookston; W. B. Torgerson, Oklee; and L. A. Williams, Slayton.

The Southern Minnesota Medical Association Medal for the best scientific exhibit displayed at the meeting was awarded to Dr. Leonard S. Arling of Minneapolis, for his exhibit on "What Is Industrial Medicine?" Dr. Arling's exhibit was cited for its excellence from the standpoint of research, timeliness and scientific accuracy.

Honorable mention was made of the exhibits of Dr. Ralph X. Rossen, Hastings, "Radio-Encephalography," and Drs. Vernon L. Hart, Wesley H. Burnham and Stuart L. Arey, Minneapolis, "Congenital Displacement of the Hip Joint." Judging were Dr. Ernest M. Hammes, Sr., St. Paul; Dr. Harold L. Gainey, Kansas City, Kansas; and Dr. Sanford S. Sisson, Jacksonville, Florida.

Presentation of Distinguished Service Medal and Citation

In recognition of his many years of service to the people and to medicine in Minnesota, Dr. Albert J. Chesley, St. Paul, Secretary and Executive Officer of the Minnesota Department of Health, was awarded the Association's Distinguished Service Medal and Citation. Presentation was made by Dr. F. J. Elias, Duluth, Chairman of the Council. The presentation speech of Dr. Elias was as follows:

DR. ELIAS: Tonight I have the very great honor of paying tribute in behalf of the entire membership of the Minnesota State Medical Association to one of its most loyal members and devoted servants. No one will deny, I am sure, that his untiring efforts in behalf of Minnesota medicine and in behalf of all of the people of Minnesota, in fact, have earned for him the highest tribute we can pay.

A staunch advocate of the preservation of private enterprise in medicine, and elsewhere, he has behind him an enviable record of nearly half a century of outstanding service in the field of public health and social hygiene, not only in Minnesota but far beyond its borders and even abroad. In fact, as we have often said about him, it would be hard to visualize health and medical activities in Minnesota over the years since he took a hand in it, without him there.

A native son of Minnesota, he was educated at our State University and since first receiving his M.D. in 1907, he has in some way been serving medicine and public health in this state. Beginning as an assistant bacteriologist with the State Board of Health as his first full-time job, he has been working for the same agency ever since. For some twenty years he was also professor of public health at the University of Minnesota department of preventive medicine.

He also served in the First World War and even before that in the Spanish-American War and the Philippine Insurrection. In 1918-19 he went to France as public health expert for the American Red Cross. In 1919-20 he served as chief of staff for the Red Cross in Poland. In 1940 he guided and planned for welfare and health protection of guardsmen in Minnesota while they trained here in the Defense Program.

He has a record for being able to plan ahead—to see the job through. Evidence of this is seen throughout all of the social hygiene work developed under his direction. He was recognized only last year with the granting of an honorary life membership to him by the American Social Hygiene Association.

And so, at this time, the Council of the Minnesota State Medical Association wishes to award its 1948 Distinguished Service Medal to Dr. Albert J. Chesley. It is a very great honor and a pleasure to confer upon him at this time this citation and this medal of which he is so richly deserving.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

(Continued from Page 1124)

and the cases were set for trial for September 13, 1948. The defendant Olson, at the time of her arrest, was employed at a Minneapolis hospital. It was the claim of the State that the defendant Conry persuaded the defendant Olson to perform the abortion. No money was paid to defendant Olson for her services. Because of the extenuating circumstances in the case, in so far as the defendant, Lucille P. Olson was concerned, the State permitted her to plead guilty to an information charging her with the crime of practicing healing without a basic science certificate, instead of abortion. This plea was entered on September 22, 1948, before Judge Carroll, who imposed a sentence of one year in the Minneapolis Workhouse and, upon the recommendation of legal counsel for the Minnesota State Board of Medical Examiners, suspended the sentence and placed the defendant on probation for a period of three years.

Minnesota Academy of Medicine

Meeting of April 14, 1948

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, April 14, 1948. Dinner was served at 7 o'clock, and the meeting was called to order at 8:10 by the president, Dr. T. A. Peppard.

There were fifty members and four guests present.

Upon ballot, the following were elected as candidates for membership in the Academy: Dr. J. R. Aurelius, Saint Paul, and Dr. Clarence Dennis, University Medical School.

The scientific program followed.

TRANSMUTATION OF A MYELOID INTO A LYMPHATIC LEUKEMIA OR AN EARLY STEM-CELL UNDIFFERENTIATED LEUKEMIA

Case Report

J. A. LEPAK, M.D.
Saint Paul, Minnesota

The patient came under observation February 3, 1943, for high blood pressure and headaches of several years duration. She was fifty-three years of age, a housewife, married and had one child. One cousin had died of leukemia. The gall bladder, tonsils and teeth had been removed. Slight constipation was present. Menstruation had ceased at forty-seven and menopausal disturbances followed. She slept poorly, took three cups of coffee daily, and weighed 166 pounds.

The physical examination showed ears, eyes, nose and throat in good condition. An upper and lower denture was present. Over the base of the heart a rough systolic murmur was heard. The abdominal findings were normal. Slight varicose veins were present on both of the lower extremities. Blood pressure read systolic 220, diastolic 110 mm. of mercury. Urinalysis was negative. The blood showed hemoglobin 80 per cent, red blood count 4,340,000, and white blood count 8,850. The electrocardiogram showed only left ventricular preponderance.

She was advised to reduce weight gradually to 150 pounds. The blood pressure under this regimen gradually dropped, fluctuating from a systolic of 130 to 170 and a diastolic of 70 to 100 mm. of mercury. Menopausal symptoms disappeared, and she remained relatively well until December 29, 1944, when precordial pain appeared following a slight upper respiratory infection, and hospitalization became imperative. At the hospital the salient physical findings consisted of râles in both bases and a blood pressure of systolic 130, diastolic 80 mm. of mercury. The electrocardiogram revealed left ventricular extrasystoles, inverted T wave in lead II, low T in lead III with left axis deviation, suggesting myocardial damage. The x-ray picture of the chest showed thoracic osteoarthritis. The blood examination showed findings as recorded in Table I.

The sedimentation rate on December 30, 1944, was 84 mm. in one hour; on January 13, 1945, it was 55 mm. She was discharged from the hospital on January 17, 1945, with a diagnosis of myelogenous leukemia. Thereafter, the blood was examined from time to time, with the findings as recorded in Table II.

After the blood examination on March 4, 1946, x-ray therapy was advised. She chose the Mayo Clinic and remained under Dr. H. C. Giffin's observation and treatment from April 1, 1946 to April 13, 1946. He confirmed the diagnosis of chronic myelogenous leukemia and gave the following findings before treatment: Hemoglobin was 11.2 gm., erythrocytes 4,200,000, leukocytes 172,000. The platelets were 283,000. The differential count was: lymphocytes 1.0 per cent, monocytes 3.5 per cent, neutrophiles 54.0 per cent eosinophiles 0.5 per cent, basophiles 4.0 per cent myelocytes 9.5 per cent, metamyelocytes 10.0 per cent, promyelocytes 9.5 per cent, leukoblasts 7.5 per cent, stem cells 0.5 per cent. Blood smears were characteristic of myelogenous leukemia.

The edge of the spleen was palpable. A rough systolic murmur was heard over the base of the heart due to aortic sclerosis. Her blood pressure was systolic 190 to 210, diastolic 100 to 110 mm. of mercury. The eye grounds showed grade I narrowing of the arterioles.

12-30-46			83,000 Mayo
1-8-47	Concluded six x-ray treatments		9,400 Clinic

Her height was 59 inches and weight 148 pounds with clothing. Urinalysis was negative. Blood urea revealed 34. mg., and the blood Wassermann test was negative. X-ray showed calcification of the aorta. Electrocardiogram revealed slurred QRS in lead II, left axis deviation, inverted T in lead III.

After receiving eight x-ray treatments at the Mayo Clinic the leukocyte count dropped to 40,000 and she returned to Saint Paul. Then the blood was checked from time to time so that she might receive further x-ray treatment if the leukocyte count should reach 50,000. Table III shows briefly the dates, blood findings and x-ray treatments.

morphonuclear cells until the transfusions were started. After the transfusions were started, 1 to 4 polymorphonuclear cells appeared in the smears. There were five transfusions, the first on January 28, 1947 and the last on February 7, 1947.

A sternal puncture was performed on January 29, 1947, and showed the following findings; fat 3 per cent, plasma 64 per cent, myeloid layer 9 per cent, erythrocytes 24 per cent. The differential count revealed 96 per cent lymphocytes, of which many showed evidence of immaturity. An occasional granulocyte and normoblast was noted, and myeloblasts were present also. The pathologist made a diagnosis of lymphatic leukemia. Dr. Thomas J. Kenyon, formerly pathologist at St. Joseph's Hospital, concluded: "(1) The blood morphology indicates a leukemia of a lymphatic type. (2) In spite of the chronicity from the clinical standpoint, the morphology suggests an acute type."

TABLE V. DIFFERENTIAL COUNTS AND PLATELETS

Date	Polymorphonuclear	Basophiles	Small lymphocytes	Large lymphocytes	Monocytes	Early	Platelets
1-21-47			7	4		89	267,000

2-10-47	1	1	18	4	5	71	

Returning home after the last x-ray treatment on January 8, 1947, gradual weakness became more and more pronounced. Nausea, vomiting, pallor, fever (104 degrees), sweating and ecchymoses appeared a few days later. These disturbances became worse, and she was sent to the hospital for further study and treatment on January 21, 1947. At the hospital, petechiae and ecchymoses increased, râles appeared in the chest and the mouth became very sore. In addition to the high fever she perspired freely and was restless. Blood transfusions, glucose and penicillin were given, but failed to stop the course of the disease. X-ray pictures of the chest were negative. On February 10, 1947, a right hemiplegia appeared, and a short time later the patient died.

The blood findings at St. Joseph's Hospital are shown in Tables IV and V and show a total absence of poly-

Discussion

Mixed leukemias have been reported by Turk, Hirschfeld, Naegeli, Browning, Herxheimer and Logefeil. This case, however, is not a mixed leukemia. It points, rather, to a retreat of the leukemic process to such an early stage in the usual course of leukemic development that the process could deviate readily and follow the lymphatic route and thus produce early lymphocytes indistinguishable from stem cells; or it is possible that these are early stem cells which could have become, if the patient had lived, either polymorphonuclear or lymphocytes.

The writer wishes to acknowledge his gratitude to the following pathologists and hematologists who studied either some or all of the blood findings:

Kano Ikeda, M.D., Pathologist, Charles T. Miller Hospital, Saint Paul, Minnesota

Thomas J. Kenyon, M.D., formerly Pathologist, St. Joseph's Hospital, Saint Paul, Minnesota

H. Z. Giffin, M.D., Clinical Section, Mayo Clinic, Rochester, Minnesota

C. H. Watkins, M.D., Clinical Section, Mayo Clinic, Rochester, Minnesota

Roy R. Kracke, M.D., Dean, Medical College of Alabama, Birmingham, Alabama

Hal Downey, M.D., Professor of Anatomy, University of Minnesota

E. T. Bell, M.D., Professor of Pathology, University of Minnesota

ENHANCING EFFECTS OF PENICILLIN

E. S. PLATOU, M.D.

Minneapolis, Minnesota

Since the introduction of penicillin, the problem of its rapid absorption and excretion has occupied the attention of many workers. Biologic methods for determining plasma levels of penicillin brought about a more precise knowledge of the concentration of the drug, but the duration of effects on bacteria *in vivo* needs further study. Large losses in the urine were recognized early when shortages required recovery and re-use. The renal clearance of commercial penicillin is 750 c.c. to 1,200 c.c. per minute, approximating that of total renal plasma flow. When crystalline penicillin G or X is given intramuscularly in aqueous solution, 60 per cent of it can be recovered in the urine by the end of an hour. Blood levels fall off at the rate of approximately 70 per cent per hour after penicillins are given in aqueous solution intramuscularly. In spite of lower renal clearance, penicillin K yields relatively low plasma levels due to an organic combination with proteins which also lessens its potency. An effective plasma concentration of penicillin mixtures is presently thought to be about 0.03 units per cubic centimeter for most penicillin-susceptible organisms. Whether a sustained level above this arbitrary minimum or a periodic "peak" is preferable has been controversial. Persistently high concentrations have been assumed to be effective in combating unusual cases with fulminating or stubborn infection; a combination of constant and "peak" effects is believed by some to be even better.

Approaches to the problem of enhancing and prolonging the effectiveness of penicillin have included such measures as:

1. Varying and multiple routes of administration.
2. Slowing absorption.
3. Blocking tubular excretion.
4. Employing selective inhibitory effects to alter tubular enzymatic mechanisms (caronamide).
5. Combining methods.
6. Reactivating insoluble penicillin salts *in vivo*.
7. Using an alternate antibiotic with slow absorption curve.
8. Varying frequency and size of dosage.

TABLE I. PENICILLIN—AVERAGE CONCENTRATION AND DURATION OF EFFECTS
10,000—25,000 U. given to infants and children

Route	Stat.	½ hr.	1 hr.	2 hr.	3 hr.	Absorption Variation

Suppression of Renal Clearance—2 to 5 fold increase						+

Modified from Kolmer, Cooke, Goldring, and Husson. Dosage, body weight, fluid intake, renal function, and method may alter levels

Varying and Multiple Routes of Administration

For the great majority of penicillin-susceptible infections, periodic levels of penicillin from 0.01 to 0.1 units per c.c. of plasma twice daily are adequate. To attain such levels, intramuscular injections of aqueous penicillin in doses of 10,000 to 25,000 units, or oral doses of 50,000 to 100,000 units, have been used successfully in infants and children.

In infections of the respiratory tract, inhalation in aerosol has been useful, particularly as an adjuvant to intramuscular administration; surprisingly high levels have sometimes been attained after inhalation alone. Bryson and Grace,[1] and Prigal[10] have reported that penicillin given in doses of 100,000 to 200,000 units suspended in aerosols of propylene glycol-glycerine, or in zephiran-glycerine alone, produces apparently adequate blood levels for as long as five hours. This mode of therapy has proved beneficial in purulent sinusitis, as well as in fibrocystic disease, intrinsic infectious asthma, bronchiectasis and other diffuse bronchial or bronchiolitic diseases. Although a suitable nebulizer, a source of oxygen and a rubber tube are adequate equipment for older children, in infants and younger children an apparatus such as that described by Prigal[10] is perhaps superior.

The method of penicillin therapy described by Bryson and Grace[1] for respiratory infections combines penicillin intramuscularly in wax and oil every twenty-four hours (300,000 units), neosynephrine by nebulizer, penicillin 100,000 units in 3 c.c. of zephiran (1:1,000 aqueous as a detergent) for inhalation every eight hours, and deep breathing to accomplish the topical principle.

Local penicillin injected into pleural, pericardial, peritoneal, and synovial cavities enhanced effects of routine administration. Similarly, in meningitis, small well-diluted intrathecal doses of 5,000 to 10,000 units have been helpful, though larger ones have sometimes been followed by immediate or late irritative and degenerative effects on the nervous system.

In thrombophlebotic lesions, i.e., osteomyelitis, sinus thrombophlebitis, subacute bacterial endocarditis, et cetera, apparent enhancement of penicillin effects has followed concomitant use of anticoagulants. Since the minute lesion of meningitis has been shown to be throm-

Because of the illness of Dr. Erling Platou, his inaugural thesis was read by Dr. Edwin Robb.

bophlebotic, the question has been raised whether anticoagulants might be considered even for this disease.

When oral penicillin was first used, variations of concentration occurred in different patients and even in the same patient from hour to hour; fluid and food ingestion were shown to influence this. It was believed that penicillin was ineffective when taken by mouth because of destruction in the stomach, irregularities in absorption, and inactivation by residual food. Experiments conducted by Finland, McDermott, Libby, Cutting and Hoffman and Volini have resulted in several interesting conclusions:

1. The oral dose of penicillin must be about five times the intramuscular dose to produce comparable blood levels for three hour periods.
2. Addition of binding or buffering substances does not increase therapeutic levels significantly.
3. Saline solutions of penicillin were more easily passed out of the stomach by spurts, causing more rapid and complete total absorption.
4. The effects of food were best minimized by giving penicillin one hour before meals, after a three- or four-hour fast.

The work of Hoffman and Volini[5] has shown that in older children and adults penicillin levels are best maintained orally by an initial dose of 200,000 units in saline followed in one hour by 100,000 units and then 100,000 units every three hours. By this plan, blood levels well above 0.03 units per cubic centimeter were maintained, although individual variations occurred. Doses of 25,000 have been reported by Husson[6] as producing adequate levels in infants.

Slowing of Absorption

Several methods of slowing absorption have been tried, including such simple physical changes as cooling the site of injection. The most effective methods developed thus far have employed suspensions in beeswax and peanut oil (Romansky formula) or in procaine and sesame oil.

The first major attempts to prolong activity of penicillin by the addition of a binding substance were made in 1943 and 1944. Beeswax was found to be best for this purpose, although it produced rather frequent tissue reactions. By using a small concentration of beeswax in peanut oil, however, it was possible to avoid most of these. Concentrations of 4 to 4.8 per cent beeswax in peanut oil were thought to produce a minimum of local inflammatory processes, and subcutaneous injection was found to be less painful than intramuscular. 100,000 units of penicillin in 1 c.c. of this mixture prolonged effective therapeutic levels of penicillin for six to eight hours after injection; 200,000 units increased absorption time slightly but 300,000 units in 1 c.c. of 4.8 per cent beeswax in peanut oil (given intramuscularly) prolonged blood levels for twenty-four hours. Less than 300,000 units per injection was considered inadequate and more than 300,000 units merely prolonged the initial peak blood level but did not give sustained concentrations of much greater magnitude.

Recent work by Dowling and Romansky[3] indicates that the greater the particle size of penicillin in an injectable mixture, the greater its effect in delaying absorption. They found that in order for a mixture to prolong absorption for twenty-four hours, at least 50 per cent of the particles in the mixture should have diameters of 50 microns or more. Because amorphous penicillin does not achieve this as well as crystalline penicillin, these investigators believe that crystalline calcium penicillin, when given intramuscularly in 2 per cent beeswax in peanut oil, produces more constant absorption and more effective blood levels than any other mixture we have at the present time.

A good body of evidence has accumulated to indicate that procaine penicillin, as proposed by Sullivan and his associates, will have an equally useful place. After injections of 1 c.c. containing 300,000 units, blood levels are usually still maintained in the therapeutic range after twenty-four hours. Up to the present time, undesirable side effects related to procaine or the menstruum of sesame oil have been conspicuous by their rarity. It is hoped that this mixture will prove to be as effective and more practical than the better-known oil-beeswax preparations.

Loewe and his associates have described a water-soluble preparation of penicillin containing gelatin-dextrose, ephedrine, and epinephrine which they claim will maintain measurable levels for twenty-four hours or longer and retain stability at room temperature for more than a year.

Blocking Tubular Excretion

About 80 per cent of penicillin is excreted by normal renal tubules and found in urine. Thus, any drug which could effectively yet harmlessly block tubules might conceivably raise plasma concentrations. Diodrast or iodypyrin (used in urography) and para-amino-hippuric acid (used in functional tests of the tubules) have been successfully administered for this purpose. Penicillin excretion can be suppressed almost completely by continuous intravenous infusion of either of these drugs, and high levels of penicillin can be obtained, though such large quantities of the inhibitors are often required that the method has been found somewhat impractical. Despite this handicap, it has accounted for some striking therapeutic results in resistant infections. Benzoic acid and sodium benzoate have also apparently enhanced plasma concentrations.

Employing Selective Inhibitory Effects on Tubular Enzymatic Mechanisms

Beyer et al introduced caronamide, believed to be wholly excreted by glomerular filtration. It probably has a selective inhibitory effect on the enzymatic mechanism of the tubules, so it suppresses tubular excretion in a manner different from the mass competition or "blocking" with diodrast or para-amino-hippuric acid.

Strauss et al[12] studied the effectiveness of caronamide and sodium benzoate individually and in combination. Sodium benzoate has been shown to have an anti-penicillinase effect which, some contend, may explain its properties more accurately than its blocking effect. Its lower

toxicity and cost might make it more desirable. The dose employed has been 1.2 gm. per 100,000 units. Caronamide is supplied in 0.5 gm. tablets and is given in doses of 0.4 gm. per kilo per day. Since it is excreted in four hours, the dose-interval should be three hours.

oral penicillin. Eighty per cent of the patients had assayable levels at twenty-four hours, after 300,000 units of intramuscular penicillin alone, the average concentration being 0.058 units per 1 c.c. at this time. Intramuscular injection of 300,000 units followed by 100,000

Some of the observations of Strauss on caronamide and sodium benzoate were to the effect that caronamide or sodium benzoate given orally enhanced the plasma penicillin concentration following either oral or intramuscular administration of penicillin. Oral penicillin in combination with both caronamide and sodium benzoate resulted in greater enhancement of the plasma penicillin concentration than was found with either of the two drugs alone. The trio was more effective than either of the pairs. Both caronamide and sodium benzoate were, however, shown to have a serious limitation. Under certain conditions they apparently accentuate the variable absorption already observed after oral administration of penicillin.

Crosson et al[2] reported that caronamide given orally "elevates" the plasma concentration of penicillin two to seven times following its oral and parenteral administration. They concluded that both oral and intramuscular administration of penicillin is greatly enhanced by the oral use of caronamide.

Seeler, Wilcox, and Finland[11] made similar observations in older subjects but noted that approximately twice the dose of caronamide was necessary to produce equivalent levels in persons of younger age groups.

Rapaport and his associates reported no toxicity due to caronamide in fifteen children. Penicillin levels were markedly elevated with doses of 0.4 gm. per kilo per day given in divided doses at three-hour intervals. Eagle contends, "To maintain an effective concentration of such blocking agents may prove no less laborious and with some of these agents no less costly than to repeat the injections of pencillin or to increase the dosage."

Combining Methods

Combined methods of penicillin administration and clearance suppression have been extensively studied. Trussel, Sinclair, and Buchanan[13] recently reported observations made after patients had received intramuscular injections of penicillin in 2 per cent beeswax in peanut oil. These were compared with levels obtained from others who received similar injections complemented by

units orally at twelve, fifteen, eighteen, and twenty-one hours yielded assayable levels in all subjects at the end of twenty-four hours, the average level at this time being 0.139 units per c.c.

Suppressed renal clearance has been most effectively accomplished to date by a combination of sodium benzoate and caronamide. Combining this suppression of renal clearance demonstrated by Strauss with the delayed absorption technique of Trussel and associates, we have attempted to raise and prolong levels in infants.

Table II reveals a tendency toward higher and more prolonged levels in infants who received penicillin in oil and beeswax and oral penicillin together with caronamide and sodium benzoate. A high "peak" is demonstrated but the number of observations is still small. Study is now in progress to determine whether this planned combination may have sufficient merit to justify its use in overwhelming infections.

Reactivating Insoluble Penicillin Salts in Vivo

After injections of silver, mercuric, and ferric penicillinates into rabbits, Monash[9] was recently able to show that these inactive and insoluble penicillins can be reactivated *in vivo*. One injection of 20,000 units of silver or mercury penicillinate produced blood levels of 0.08 units per c.c. at seventeen hours; one of ferric penicillinate, a level of .16 units per c.c. at seventeen hours. Similar blood levels were also recorded after the use of organic substances such as brilliant green penicillinate.

Using An Alternate Antibiotic with a Slow Absorption Curve

Eagle and his associates[4] have studied bacitracin. This substance, discovered by Johnson, Anker, and Meleny[8] in culture filtrates of B. subtilis, possesses bactericidal properties and has a low renal clearance. Although samples studied to date are gravimetrically only one-twelfth as active as penicillin G *in vitro*, in this respect its slower excretion and resulting higher blood level raises the hope that similar preparations may eventually be forthcoming.

Varying the Frequency and Size of Dosage

Following development of biologic tests to determine plasma concentration of penicillin accurately, and later general acceptance of a therapeutic threshold of 0.03 units per cubic centimeter, there has developed a tendency towards attempting to maintain concentrations at or above this therapeutic minimum without consideration for duration of bacteriostatic effects.

It has recently been observed that "periodic peaks" of penicillin are probably adequate alone for many, if not most, Gram-positive infections. Experiments of Jawitz[7] appear to show that the effects of penicillin on streptococcal infections in the mouse last much longer than measurable blood concentrations. Assayable levels persisted for only one hour after injection of the drug, while depression of bacterial population continued for eight hours or longer. Zubrod[14] investigated the relative efficacy of different dosage schedules of penicillin in beta hemolytic streptococcal infection of mice. He found that in treatment with multiple doses of aqueous penicillin, survival depends more on total dose administered than on the number of fractions into which the total dose is divided. Marshall states that the maintenance of a constant blood concentration is probably unnecessary for efficient therapy in the human. He believes that it should be possible to accomplish satisfactory therapy with aqueous penicillin given in even one, two or three injections per day. After all, bacteriostasis is but a part of the recovery mechanism. Recently, large doses of aqueous penicillin given every twelve hours have been reported by several clinics to be very effective.

Levels so obtained may not be adequate to combat all bacterial infections. Sustained very high concentrations of penicillin (possibly augmented by "peak" doses) appear to be the best available direct method for attacking severe infections. Strain resistance to penicillin *in vivo* has rarely been observed as an acquired characteristic even following exposure to subcurative doses of antibiotics. Penicillin resistance usually develops slowly and is not a frequent clinical problem. Mixed infection more commonly explains what may seem like strain resistance. The need for unusual enhancement of effects is therefore not common. When naturally resistant mutants are suspected, solution of resultant problems should be sought in clinical judgment and biologic tests for strain susceptibility. The dosage and method of administration of penicillin should be planned in such a manner as to eliminate both susceptible and naturally resistant variants as rapidly and as completely as possible.

Summary and Conclusions

1. Adjuvant or multiple routes of administration of penicillin result in additive effects.

2. Slowing absorption by injecting suspensions of large crystalline particles of penicillin in beeswax and peanut oil, or in procaine and sesame oil, offer methods for maintaining increased levels.

3. Blocking of tubular excretion with diodrast or para-amino-hippuric acid enhances penicillin levels but is still impractical.

4. Suppression of renal clearance with sodium benzoate and caronamide will elevate plasma levels of penicillin in most instances.

5. Combined methods for slowing absorption and suppressing renal clearance are still in the experimental stage.

6. The reactivation of insoluble penicillin salts may prove to be useful, and more effective antibiotic agents having lower renal clearances may yet be developed.

7. Aqueous solutions of injectible or oral penicillin in large infrequent doses are probably adequate for most infections due to susceptible organisms.

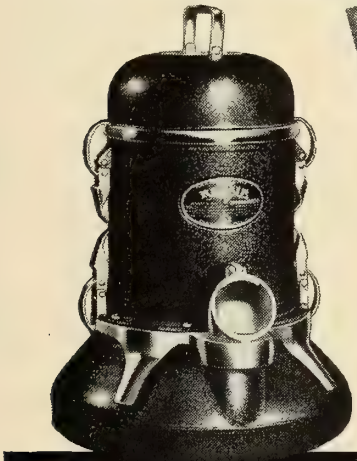
of investigation and lead automatically to full membership after a year. Also, letters were sent by the Society's secretary to all the local hospitals urging that returned servicemen be accommodated to the fullest extent. Other localities might well follow this example.

If there are localities in which established doctors are throttling competition by preventing hospital appointments for beginners, the hospital staffs constitute the agency for correcting the situation. Local societies might well review their attitudes toward strangers locating in their communities, with a view to revising provisions of constitutions where indicated.

Would You Use a Screen to Collect Dust?



Of course you wouldn't collect dust in a screen. If you did, fine dust would filter through the holes of the screen, back into the air and onto the surfaces you had just cleaned.

Using a bag or filter to collect dust is like gathering dust in a screen. The bag must be porous to let the air escape. When the air escapes, dust escapes with it. You actually take dust from the floor and throw it into the air you breathe!

Rexair, the new home appliance, solves this problem by collecting dust in water instead of a bag. Rexair takes dust wherever it is found—on rugs, bare floors, upholstery, furniture, drapes—and traps it in a water bath. Rexair even takes dust from the air you breathe.

Wet dust cannot fly, and dust cannot escape from Rexair's water basin. You simply pour the water down the drain, and dirt goes with it—out of your house forever.

FREE BOOK—Send for this colorful, illustrated 12-page book. Shows how Rexair does all your cleaning jobs, and even washes the air you breathe. Ask for all the copies you can use. No obligation.

Reports and Announcements

INTERSTATE POSTGRADUATE MEDICAL ASSOCIATION OF NORTH AMERICA

The International Medical Assembly of the Interstate Postgraduate Medical Association will be held November 9 to 12, 1948, at the Public Auditorium in Cleveland, Ohio.

The program this year, as in former years, will consist of diagnostic clinics and addresses at the morning, afternoon and evening sessions by outstanding educators and clinicians from this and foreign countries. Extensive commercial exhibits will be on display.

The registration fee for the four-day session is $5.00. Doctors in uniform, interns, nurses, dietitians and technicians will be admitted upon the payment of $1.00.

The officers of the Association this year are: Dr. Herman L. Kretschmer, Chicago, president; Dr. Evarts A. Graham, St. Louis, president-elect; Dr. John F. Erdmann, New York, and Dr. Frank H. Lahey, Boston, presidents of clinics.

Hotel reservations should be made through the Housing Bureau for Interstate Postgraduate Medical Assembly, 511 Terminal Tower, Cleveland 13, Ohio.

AMERICAN COLLEGE OF SURGEONS

The thirty-fourth clinical congress of the American College of Surgeons will be held from October 18 to 22, 1948, in Los Angeles, with headquarters at the Biltmore Hotel. Surgeons from thirty-two states, two Canadian provinces and one from Sweden, Dr. Crafoord of Stockholm, will participate in the program. The research work of some 250 surgeons and their assistants will be reported at the eight sessions of the Forum on Fundamental Surgical Problems.

Twenty-four hospitals in Los Angeles and vicinity will hold operative and nonoperative clinics, and telecasts of operations from the Los Angeles County Hospital will be shown each day at the Biltmore Hotel.

Dr. Dallas B. Phemister of Chicago will be inaugurated as president of the college to succeed Dr. Arthur Wallen of Boston. Dr. Howard A. Patterson of New York will be elected first vice president, Dr. Carl H. McCaskey of Indianapolis, second vice president, and Dr. Paul B. Magnuson of Washington continues as secretary.

NORTHERN MINNESOTA ASSOCIATION

The twenty-eighth annual meeting of the Northern Minnesota Medical Association was held in Duluth on August 20 and 21.

Among subjects discussed in papers presented at the two-day meeting were surgery of the colon, electrocardiograms, abnormal pregnancy, treatment of burns, infant diseases, and general medical diagnosis. Speakers included Dr. Wilford J. Deweese, Bemidji; Dr. Arthur C. Kerkhof and Dr. Tague C. Chisholm, Minneapolis; Dr. B. Marden Black and Dr. Walter C. Alvarez, Rochester; Dr. N. Logan Levin, Saint Paul, and Dr. Earl E. Barrett, Duluth.

A clinical-roentgen-pathological conference, arranged by Dr. E. L. Tuohy and Dr. Henry G. Moehring, Duluth, was a feature of the second day of the meeting.

Principal speaker at the annual banquet, held in Hotel Duluth on August 20, was Senator Joseph H. Ball, who attacked the proposed Wagner-Murray-Dingell bill, declaring that it would result in "medical dictatorship" by the government. Other speakers at the banquet were Dr. A. E. Cardle, Minneapolis, and Dr. E. M. Hammes, Saint Paul, president and president-elect, respectively, of the Minnesota State Medical Association.

At a business session, the association members elected Dr. R. H. Puumala, Cloquet, president of the group to succeed Dr. Charles W. Vanderslius, Bemidji. Other offices named were Dr. Wilford J. Deweese, Bemidji, vice president, and Dr. C. L. Oppegaard, Crookston, secretary-treasurer. Alexandria was selected as the meeting place for the 1949 convention.

MINNESOTA SOCIETY OF NEUROLOGY AND PSYCHIATRY

Two scientific papers were presented at a meeting of the Minnesota Society of Neurology and Psychiatry held at the Minnesota Club in Saint Paul on September 14.

Dr. Ernest M. Hammes, Jr., presented an inaugural thesis on "Familial Periodic Paralysis," and Dr. Marvin Sukov gave as his inaugural thesis a paper on "Observations on Teaching Psychotherapy."

A NEW REHABILITATION CENTER

A new therapeutic center, the St. Paul Rehabilitation Center, has been established at 279 Rice Street, St. Paul. Physical therapy, occupational therapy, and speech therapy are given in unified service by qualified therapists.

Conditions treated include industrial injuries, infantile paralysis, fractures, cerebral palsy, arthritis, neuritis, amputees, paraplegias, skin disorders, congenital defects, contractures resulting from burns, and postural and structural defects of muscles, bones, and joints. Speech disabilities treated include delayed speech, sound substitutions, speech of the hard of hearing, cleft palate speech, cerebral palsy speech, aphasic speech, voice disorders, and stuttering. Throughout the Center new modern therapeutic equipment has been installed.

The aims of the Center are prevention of unnecessary handicaps, hastening of rehabilitation, restoration of function if possible, utilization of residual function, and adjustment of patient to any residual disability. All admissions are made upon the referral of medical doctors.

The medical policies of the Center are guided by a Medical Advisory Board which consists of seven doctors appointed by the Ramsey County Medical Society.

An Executive Committee formulates policies. This committee is composed of representatives from the initiating agency, the Family Nursing Service, and the three sponsoring agencies, the Minnesota Society for Crippled Children and Adults, Inc., Junior League of St. Paul, Inc., and the Wilder Charity.

middle age + mental ease

The woman in the climacterium may be disturbed by disquieting thoughts and foolish fears. Such mental anguish is oftentimes allayed when the physical symptoms associated with declining ovarian function have been relieved.

*"**Premarin,**" by bringing about remission of menopausal symptoms, restores mental ease in a majority of instances. Furthermore, there is a "plus" in "**Premarin**"...the gratifying "sense of well-being" usually experienced by the patient following administration of this naturally occurring, orally active estrogen.*

*Flexible dosage regimens to adapt treatment to the particular needs of the patient are made possible with "**Premarin**" Tablets of 2.5, 1.25, or 0.625 mg., and liquid—0.625 mg. per 4 cc. (one teaspoonful).*

*While sodium estrone sulfate is the principal estrogen in "**Premarin,**" other equine estrogens...estradiol, equilin, equilenin, hippulin...are probably also present in varying amounts as water soluble conjugates.*

In Memoriam

ROBERT EARL

Dr. Robert Earl, a practicing physician in Saint Paul for more than fifty years, died August 11, 1948.

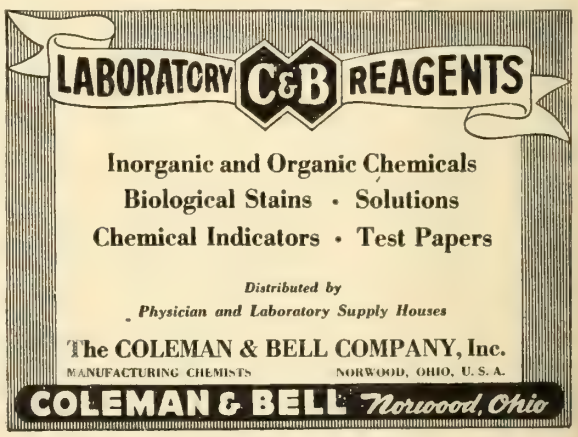
Robert Earl was born in Lansing, Iowa, on August 27, 1872. He moved to Minneapolis at ten years of age. He graduated from the University of Minnesota Medical School in 1896 and interned at Bethesda Hospital, Saint Paul, where he began a fruitful period of surgical training under Dr. Edouard Boeckmann and Dr. E. M. Lundholm. He received a diploma from the New York Post Graduate School and in 1911 spent a year of study in Europe, especially in the field of brain surgery. As a result, he was one of the first surgeons in this region to interest himself in the field of neurosurgery. This was essential to the development of a neurological and psychiatric center at Mounds Park Sanitarium in collaboration with such early neurologists as Dr. Eugene Riggs and Dr. Charles Ball.

Dr. Earl was instrumental in having the Gillette State Hospital located in Saint Paul and for years was very active on the surgical staff. In 1910 Dr. George Earl became associated with Dr. Robert Earl in the practice of medicine, from which association the Earl Clinic developed.

Dr. Earl was a Diplomate of the American Board of Surgery, a Fellow of the American College of Surgeons, a member of the Western Surgical Association, the American Medical Association, Minnesota State Medical Association, Minnesota Academy of Medicine, the Saint Paul Surgical Society and the Ramsey County Medical Society, of which he was president in 1918. He recently became a member of the Fifty Club of the Minnesota State Medical Association.

Dr. Earl is survived by his wife; a daughter, Mrs. James Slocum of Minneapolis; a son, Dr. John Earl of Saint Paul; five grandchildren; two sisters, Emily Earl and Mrs. Hilda Anderson of California, and a brother, Dr. George Earl of Saint Paul.

LEONARD EASTON CLAYDON



Dr. L. E. Claydon, a physician and surgeon of Red Wing, Minnesota, since 1902 and well known as a musician and traveler, died at his home August 15, 1948. He was seventy-nine years of age.

Dr. Claydon was born in Redditch, England, April 5, 1869, and came with his parents to Perham, Minnesota, in 1879. He graduated from the University of Minnesota School of Pharmacy in 1885, and for three years was pharmacist at the Northern Pacific Beneficial Association Hospital at Brainerd. Studying medicine at the University of Minnesota Medical School, he graduated in 1895. He practiced at Mazeppa, Minnesota, from 1895 until 1902, when he moved to Red Wing. Associated at one time with Doctors Cremer and Johnson, he later formed the Claydon Clinic with his son, Dr. Donald R. Claydon. Upon the latter's death in 1941, another son, Dr. Howard Claydon, became associated with him in practice.

Dr. Claydon was a member of Christ Episcopal Church, the Red Men's Club, the Elks Club, Masonic Lodge, Order of the Eastern Star, Odd Fellows, Workman Lodge and the AOUW. He was also a member of the Goodhue County Medical Society, the Minnesota State Medical Association, the American Medical Association and the Southern Minnesota Medical Association.

Dr. Claydon was fond of traveling and made his first trip abroad in 1900. In 1909 he went to Sweden; in 1914 to the Holy Land; in 1922 to South America; in 1924 to England and France; in 1926 to Panama; in 1928 to Europe; in 1930 to Russia, and in 1937 to South America. In addition, he circled the globe three times. His daughter, Marjorie, who accompanied him on his trip around the world in 1920, wrote a book on their experiences entitled "Around the World with Dad."

Dr. Claydon is survived by his wife, a son, Dr. Howard Claydon, a brother, P. H. Claydon, and a sister, Mrs. Carl Bull, of Wolf Point, Montana. His daughter, Marjorie, and son, Dr. Donald R. Claydon, preceded him in death.

BETTER VISION — with MAY-O-LITE

It's an established fact that surface reflection is one of the biggest handicaps of those who wear glasses. Reflections produce "ghost images," confusion, and eye-strain.

By the application of Low Reflection Lens Coating to the surface of your lenses, 75 to 90% of these out-of-focus reflections are converted to useful transmitted light. This coating is harder than glass.

As a refractionist you are chiefly concerned with bettering the vision of your patients. In that interest, consider this information.

May-O-Lite Low Reflection Coating reduces surface reflection; eliminates out-of-focus 'ghost images'; hardens the lens surface, thereby reducing surface scratches; improves image definition—lessens eye strain.

Each of these factors represents a possibility of better vision for your patients. You can investigate that possibility and explain it to your patients.

Low Reflection Lens Coating is available through most manufacturing and dispensing opticians. Write for a descriptive pamphlet and a treated sample of glass, today.

Of General Interest

Dr. Clyde E. Wilson, Blue Earth, was elected president of the Blue Earth school board at a meeting held during the summer.

* * *

Dr. J. R. Hodgson, Rochester, spoke on "Roentgenologic Diagnosis of Lesions of the Gastrointestinal Tract" at a meeting of the Third District Medical Society in Estelline, South Dakota, on August 12.

* * *

Dr. Winchell McK. Craig, Rochester, was elected president of the Harvey Cushing Society, named after the pioneer in neurosurgery, at a meeting held in San Francisco in August.

* * *

Dr. and Mrs. A. W. Adson, Rochester, journeyed to Honolulu, Hawaii, early in September, where Dr. Adson spoke before delegates to the Pan Pacific Surgeons Conference.

* * *

The partnership of Dr. A. J. Emond and Dr. J. S. Emond, Farmington, was announced dissolved on August 20. The brothers are continuing individual practice in their offices in the Emond Hospital building.

* * *

Dr. A. W. Nuetzman, Faribault, attended a dinner meeting of designated medical examiners of the Civil Aeronautics Administration in Minneapolis on September 3.

* * *

A former Winona resident, Dr. Richard J. Wagner began a fellowship in surgery at the University of Minnesota Hospitals during the middle of August. He completed his internship at Swedish Hospital in Minneapolis in June.

* * *

More than 150 persons attended a homecoming reception in honor of Dr. Magnus C. Peterson, superintendent of the Rochester State Hospital, in the state hospital auditorium on August 17. Dr. Peterson had recently returned from a two-month tour of Europe.

* * *

Dr. John J. McLeod, Jr., formerly of Birchwood, Wisconsin, began practice on August 3 at the clinic of Dr. James A. Cosgriff in Olivia. A graduate of the Marquette University School of Medicine, Dr. McLeod served his internship at St. Mary's Hospital, Duluth.

* * *

On September 9, Dr. Vernon L. Hart, Minneapolis, left New York to travel to the American Occupied Zone of Germany to spend six weeks taking part in a teaching program in various American hospitals. During the teaching program, Dr. Hart served as a civilian consultant for the office of the Surgeon General.

* * *

Formerly of Le Centre, Dr. Leonard Prochaska became associated in practice with Dr. A. A. Brink of Baudette in August. Dr. Prochaska, a graduate of the Marquette University School of Medicine, has studied at Minneapolis General Hospital.

* * *

A former native of Zumbrota, Dr. Robert J. Anderson became medical director and chief of the tuberculosis control section of the U. S. Public Health Service on September 1. Dr. Anderson, living in Washington, D. C., had been assistant chief of the section since 1946.

* * *

Though plans had not been definitely made, it was announced on August 12 that Hills would soon have a resident physician, the first since 1940. A Dr. Barr of Sioux Falls had indicated that he would like to conduct a medical practice in the city.

* * *

Superintendent of the Mineral Springs Sanitarium, Dr. Karl H. Pfuetze spoke at a meeting of the Rotary Club in Stillwater on September 2. Dr. Pfuetze discussed some of the phases of operation of the institution he heads.

* * *

West-Central Minnesota Health Day was held in Willmar on September 9. Among physicians appearing on the program were Dr. B. O. Mork, Jr., Worthington; Dr. W. W. Yaeger, Marshall; Dr. Robert Barr, Minneapolis, and Dr. B. J. Branton and Dr. Lloyd Gilman, both of Willmar.

* * *

At the meeting of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons, held early in September at Hot Springs, Virginia, Dr. R. D. Mussey, Rochester, presented the presidential address, and Dr. L. M. Randall, Rochester, spoke on the subject, "Elderly Primigravid Women."

* * *

Two Rochester physicians presented papers at a meeting of the Boone-Story County Medical Society at Ames, Iowa, early in September, Dr. D. O. Ferris spoke on "Traumatic Injuries of the Genito-urinary Tract," while Dr. H. M. Odel's subject was "Objectives in the Management of Acute Renal Failure."

* * *

Near the end of August, Dr. John Smyth, after half a year as an associate in practice with Dr. F. H. Baum-

DECHOLIN HYDROCHOLERESIS Encourages Biliary Tract Drainage

● **Percentage Increase in Composition and Quantity of Bile Flow**

Ivy, A. C., et al: Am. J. Dig. Dis. 7:333 (Aug.) 1940.

HYDROCHOLERESIS—

an increased production of thin liver bile—is a desirable approach to therapy of non-obstructive biliary tract disturbances.

DECHOLIN—

by producing an increased flow of bile—washes stagnant, infected bile from the intrahepatic and extrahepatic biliary passages, removing pus-laden material and discouraging the ascent of infection.

HOW SUPPLIED:

Decholin in 3¾ *gr. tablets. Packages of* 25, 100, 500 *and* 1000.

Decholin

gartner in Albany, announced that he intended to move soon to Lester Prairie to open his own practice. Before he began his practice in Albany with Dr. Baumgartner, Dr. Smyth served a tour of duty in the navy.

* * *

While attending a meeting of the American Association of Blood Banks in Buffalo, New York, late in August, Dr. T. H. Seldon, Rochester, presented a paper entitled "Ways and Means of Obtaining Sufficient Donors." During a business session of the meeting, Dr. Seldon was elected vice president of the group.

* * *

Dr. A. C. Anderson, formerly of Winsted, has taken over the practice of Dr. R. E. Erickson in Hector. A graduate of the University of Minnesota, Dr. Anderson practiced for the past two years in Winsted after spending two years in the army. He began his duties in Hector on August 30.

* * *

The Northfield clinic, conducted by Dr. R. F. Mears and Dr. Joseph C. Belshe, in August, opened branch offices in Randolph. It was announced that remodeling of the front of the main office in Northfield was scheduled for early this fall. Recently the interior of the building was completely redecorated and remodeled.

* * *

As guest speaker at the Midsummer Radiological Conference of the Rocky Mountain Radiological Society, held in Salt Lake City during August, Dr. J. D. Camp of Rochester presented two papers entitled "Sources of Error in Encephalography and Ventriculography" and "Significant Roentgenologic Findings in Intracranial Disease."

* * *

A former Benson resident, Dr. Cassius J. Van Slyke was named director of the National Heart Institute early in August. A graduate of the University of Minnesota Medical School in 1927, Dr. Van Slyke has been associated with the U. S. Public Health Service since 1932. He has directed the research grants-in-aid and the fellowship program of the National Institute of Health since 1945.

* * *

Dr. Dale Furnell, formerly of Saint Paul, has become associated in practice with Dr. W. J. Lund at the Northern Pacific Clinic in Staples. A graduate of the University of Minnesota Medical School in 1945, Dr. Furnell has studied at Ancker and Abbott Hospitals and has served as a resident physician at the Northern Pacific Hospital in Saint Paul.

* * *

Plans were made in August to hold a Health Day in Mankato on October 13. The program for the event listed round-table discussions, health movies, talks on community health problems, and addresses on numerous health topics by physicians, public health nurses, school

representatives and mental hygiene experts. An address by Governor Luther Youngdahl was scheduled for the evening program.

* * *

Soloist at a Pop concert in Saint Paul on August 25 was Dr. Charles Peluso, Minneapolis, making his first solo appearance at the concerts since 1945 when he was presented on a program while on leave from the navy. A graduate of the University of Minnesota Medical School, Dr. Peluso served his internship at St. Luke's Hospital in Duluth.

* * *

Dr. Harold R. Mundall has opened an office at 1812 Selby Avenue, Saint Paul, for the practice of medicine. Dr. Mundall graduated from Marquette University Medical School in 1945 and served in the Army three years, being stationed at the tuberculosis hospital at Waukesha, Wisconsin, and at the Veterans' Hospital at St. Cloud before his discharge June 3, 1948. He was commissioned as a captain.

* * *

On August 16, Dr. Frederich G. Gunlaugson, a former staff member of the Fergus Falls State Hospital, joined the staff of the Minneapolis Health Department as director of communicable disease control, filling a post that had been empty for almost a year. Dr. Gunlaugson is a graduate of the University of Minnesota and Johns Hopkins University. He has practiced medicine in Moorhead.

* * *

It was announced on August 5 that Dr. Harry L. Berge, of Isle, had become a part-time assistant of Dr. W. F. Nordman in Mora. A graduate of the University of Minnesota Medical School, Dr. Berge studied surgery for two years at Minneapolis General Hospital. He has served as chief of surgery at Mason General Hospital, Long Island, New York, and as acting chief of surgery at Camp Lee, Virginia.

* * *

The marriage of Dr. Harry J. Anderson, formerly a resident of North Branch, and Miss Darlene Mortenson, formerly of Benson, took place on August 21 in the chapel at Fort Snelling. Dr. Anderson, a graduate of the University of Minnesota Medical School, is a resident physician in the Department of Psychiatry and Neurology at the University Hospitals and Veterans Hospital, Minneapolis.

* * *

Dr. and Mrs. Anderson Hilding, Duluth, left for Europe on August 27 to attend the 1948 conference of the Collegium Oto-Rhino-Laryngologicum Amicitiae Sacrum held September 1 to 5 in Copenhagen, Denmark. The collegium, an international research society, was resuming its annual meetings after a nine-year wartime suspension. Following the conference in Copenhagen, Dr. and Mrs. Hilding went on a trip through Sweden.

Among other events, three panel discussions were held, covering the following topics: "Our Community Health Problems," "How Can We Prevent Behavior Problems in Children?" and "The School's Part in Your Child's Health." Included in those appearing in the discussions were Dr. Mario Fischer, Duluth, and Dr. Edward Anderson, Minneapolis.

* * *

Expansion of the public health nursing service in Nobles County was announced on July 22 by Dr. B. O. Mork, Jr., Worthington, medical director of Public Health Unit No. 5. It was stated that a second public health nurse, Anna Marie Christman, formerly of Glen Lake Sanatorium, would assume her duties in Nobles County on September 1, thus bringing the county a step closer to the ideal proportion of one nurse for each 5,000 persons in the population.

* * *

Dr. Albert Faulconer, Jr., Rochester, spoke on "The Treatment of Anoxic Encephalopathy" at a meeting of the Kansas City Society of Anesthesiologists in Kansas City, Missouri, on September 8. The following day he presented two papers before the Kansas Society of Anesthesiology and the Salina County Medical Society. Titles of the papers were "Choice of Anesthetic Agent and Method" and "Some Factors Influencing the Administration of Inhalation Anesthesia."

* * *

Lake County, with a record of no tuberculosis deaths in 1947, was given special recognition at a ceremony held at a Rotary Club meeting in Two Harbors on August 17. Accreditation certificates were presented by Dr. Mario Fischer, Duluth, acting director for Health District No. 4 of the Minnesota Health Department, and a Christmas Seal plaque for individual service was awarded by Dr. E. A. Meyerding, executive secretary of the Minnesota Public Health Association.

* * *

Early in August, Dr. Wallace Hill, formerly of South Bend, Indiana, arrived in Windom to become an assistant to Dr. L. J. Hoyer in the Hoyer Clinic. Dr. Hill, a graduate of McGill University Medical College in Montreal, Canada, recently completed two years of study in Memorial Hospital, South Bend. Previously he served in the navy for two years. While Dr. Hoyer and his family were on a two-week vacation in August, Dr. Hill conducted the Windom practice.

* * *

A hypodermic injection technique that takes "all the sting out of shots" was described this summer in a letter written to the *Saturday Evening Post* by a patient of Dr. Alma L. Wurdemann of White Bear Lake. The method, not unknown to many physicians, is useful in eliminating the fear that many people have of the hypodermic needle. The injection is preceded by a series of sharp slaps with the left hand on the selected site; then, between slaps, the needle is slipped in with the right hand. Often, then, the injected patient, if he hasn't been watching, looks up and asks, "When you going to shoot me, Doc?"

Announcement has been made of the gift of $13,600,000 by the A. W. Mellon Educational and Charitable Trust to the University of Pittsburgh for a new graduate school of public health to be headed by Dr. Thomas Parran, former Surgeon General of the U. S. Public Health Service. The graduate school will emphasize occupational and industrial health and research in all phases of public health. The school will serve as a postgraduate school for the training of physicians in public health work and for conducting basic research.

* * *

"The Use of Gelatin Foam in Thoracoplasties" was a topic discussed by two Minnesota physicians at the thirty-fifth annual Mississippi Valley Conference on Tuberculosis, meeting with the Mississippi Valley Trudeau Society in St. Louis on September 26. Dr. G. A. Hedberg, superintendent of the Nopeming Sanatorium, and Dr. William D. Seybold, Rochester, described how "gelfoam" delays lung re-expansion in thoracoplasties, permitting rib restoration to take place more satisfactorily.

* * *

Dr. R. H. Monahan, Jr., of the International Falls Clinic, left the city of International Falls on August 20 to begin a three-year fellowship in ophthalmology at the University of Minnesota Hospitals. His practice at the clinic was taken over by Dr. F. H. Walter.

A native of International Falls, Dr. Monahan was graduated from the University of Minnesota Medical School in 1943. During the war he was in the army, serving part of the time as an eye specialist in Fitzsimons General Hospital in Denver, Colorado, and part time as an eye consultant with the army in northern Italy.

* * *

After forty-six years of practice in Red Wing and vicinity, Dr. A. E. Johnson, head of the Red Wing Clinic, retired from active medical practice on August 1. A graduate of Rush Medical College, Chicago, in 1902, Dr. Johnson has devoted his entire medical career to his practice in Red Wing. He has been associated with the Red Wing City Hospital for thirty-five years. Now, seventy-two years of age, Dr. Johnson has purchased a residence in Minneapolis and plans to make his future home there.

* * *

Dr. Oscar Daignault, Benson, who retired from active practice on May 1, was honored by the Benson Chamber of Commerce at a ceremony on August 16. In commemoration of his forty-eight years of service to Benson as physician and civic leader, Dr. Daignault was presented with a bronze plaque citing his achievements.

A graduate in 1898 of the Montreal Medical School, a part of the University of Laval, Dr. Daignault first practiced in Saint Paul, then in Dayton and Hancock. In 1900 he moved to Benson, where he has remained for the last forty-eight years.

* * *

As director of the Commission on Liver Disease of the Army Epidemiological Board, Dr. C. J. Watson, chairman of the Department of Medicine of the University of Minnesota Medical School, journeyed to Germany in September to survey the liver disease re-

search program of the army and to teach and lecture on recent developments in the field. He visited hospitals at Bayreuth, Munich, Mainz, Frankfurt, Nuremberg and Heidelberg. Before returning to Minneapolis late in September he spent several days in London visiting hospitals and laboratories.

* * *

A bronze plaque was recently awarded to W. D. Price, president of the Saint Paul Mercury Indemnity Company, by the National Safety Council for the motion picture film, "Diagnosis: Danger." The film illustrates the hazards in hospitals and stresses accident prevention. It was judged the best non-theatrical film in the occupational safety field during 1947. Don Hawkins, Assistant Secretary of the Saint Paul Company, wrote the script and supervised production of the sound picture. Free bookings may be secured by writing the Safety Engineering Department, Saint Paul Mercury Indemnity Company, 111 West Fifth Street, Saint Paul, Minnesota.

* * *

Angling for radioactive fish in Bikini lagoon, site of atomic bomb tests two years ago, was described early in September by Dr. Asher A. White, clinical assistant professor of medicine at the University of Minnesota. During the past summer Dr. White spent almost a month as medical advisor with a marine biology division conducting a survey of long-range atomic bomb effects. All types of the lagoon's plant and animal life were captured by the research group to be studied for signs of still-present radioactivity. During the war Dr. White was executive officer of the Oak Ridge, Tennessee, hospital and later medical officer in charge of health and welfare at the Hanford, Washington, plutonium plant.

* * *

In late August, Dr. H. B. Roholt left Waverly to begin medical practice in Fosston. Since his graduation from the University of Minnesota Medical School, Dr. Roholt had been associated in practice with his father, Dr. C. L. Roholt, in Waverly. At his new practice in Fosston he is in charge of a twenty-bed hospital, with his offices located in the hospital.

* * *

Forest Lake acquired a new physician on August 26 when Dr. R. A. Knudson, formerly of Chicago, arrived in the city to become associated in practice with Dr. J. A. Poirier. Dr. Knudson has been on the staff of a hospital in Louisville, Kentucky, and has studied at Cook County Hospital in Chicago. He served in the armed forces for two years.

* * *

Chief of staff at the Sister Elizabeth Kenny Institute in Minneapolis is Dr. E. J. Huenekens, former chairman of the Minneapolis emergency poliomyelitis committee during the 1946 epidemic, who was named to the position on August 18. He is a clinical professor of pediatrics at the University of Minnesota.

At the same time it was announced that Dr. Miland

E. Knapp, clinical associate professor of physical medicine at the University of Minnesota, had been appointed chief of physical medicine in charge of treatment at the institute. It was also stated that Dr. John F. Pohl, former medical supervisor of the institute, would be consulting orthopedic surgeon for the organization. Dr. Pohl is a clinical assistant professor of orthopedic surgery at the University of Minnesota.

HOSPITAL NEWS

Physicians and nurses of the Blue Earth Community Hospital staff met for dinner at the Riverside Town and Country Club on August 20. During the evening program, medical motion pictures were presented, and Dr. George Drexler, Blue Earth, showed a motion picture he had taken while stationed on New Britain during the war.

* * *

The Northern Minnesota Hospital in International Falls was closed on July 24 after nearly forty years of use in the community. The hospital, which was opened in 1909, has been replaced by the new International Falls Memorial Hospital.

* * *

Formerly of St. Cloud, Dr. Stanley Peterson has become resident radiologist on the staff of the St. Olaf Hospital in Austin. He replaces Dr. J. P. Medelman, Saint Paul, who for several years spent one day per week at the hospital as x-ray consultant.

* * *

A committee from Clarkfield, including Dr. M. I. Hauge, met with members of the Minnesota Department of Health in Minneapolis on August 17 to present plans for the Clarkfield hospital project. The plans were accepted with a few alterations, and it was expected that bids for the project would soon be asked.

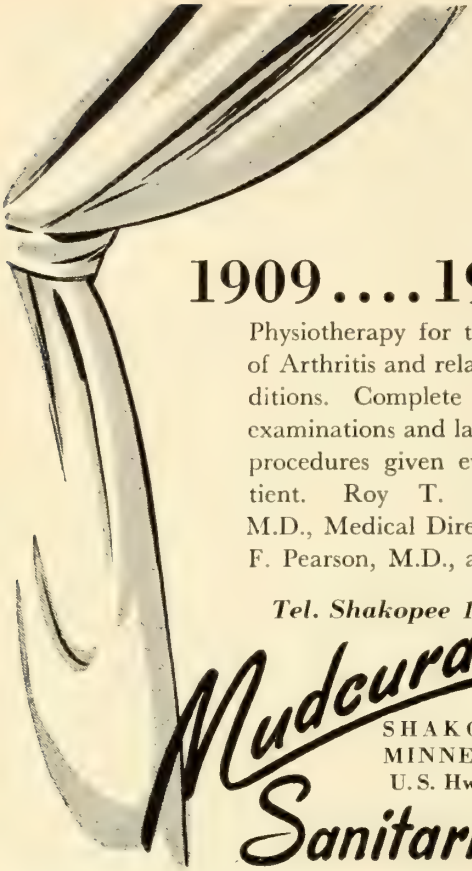
BLUE SHIELD NEWS

Number of applications received for Blue Shield to August 31, 1948, 80,000
Number of Blue Shield cases paid from August 1 to August 31, 1948, 361. Total for 1948, 1414
Amount paid on Blue Shield cases from August 1 to August 31, 1948, $13,002.63. Total for 1948, $52,577.47

For some months the Minnesota Blue Shield office has been making payments on cases once a week. The policy of making payments on a weekly basis was announced in the Blue Shield article published in the May issue of MINNESOTA MEDICINE. By making weekly payments we are able to give better service to the physician and to the subscriber, and it is also possible for the physician to show the Blue Shield allowance on his monthly statement.

During the last month the Blue Shield office has received an increasing number of claims on which prompt payment could not be made because of the fact that the attending physician's office had returned the forms either not fully completed or with insufficient information. As an example, the hospital discharge date is often omitted; this information is necessary to compute the length of stay in the hospital. Frequently there is no listing of the type of service rendered, particularly in surgical

AT YOUR CONVENIENCE, DOCTOR . . .



you are cordially invited to visit our new and modern prescription pharmacy located on the street floor of the Foshay Tower, 100 South Ninth Street.

cases. The diagnosis is given; however, it is difficult to determine if the case is medical or surgical and if surgical what procedure was carried out.

When claims are received with insufficient or incomplete information it is necessary to contact the physician for this additional information. This definitely retards our payment on the case; it means the physician must again check his records and it requires further correspondence by the physician's office as well as the Blue Shield office.

Doctors, you have done very well in completing forms and in giving the necessary information and those of us who work with this information sincerely appreciate your co-operation. In order that Blue Shield allowances can be paid in the shortest possible time and with the least amount of effort please complete the forms so that no correspondence is necessary.

In the event you have some outstanding Blue Shield cases on which you have received Medical Service Report forms, please complete them at your earliest convenience and submit them to the Blue Shield office for payment. Also, if you have rendered a Blue Shield service to a Blue Shield subscriber or dependent and have not received a form from the Blue Shield office, notify the office by letter giving the patient's name, address, group and contract number so that an investigation can be made on that case.

As more and more citizens of Minnesota become Blue Shield subscribers—and more and more are every day—the administrative problems of Blue Shield will increase. Many of these problems will be eliminated if the physicians of Minnesota continue to back their prepaid medical care plan as they have been doing and also if they continue to co-operate in the future as well as they have in the past.

PHI DELTA EPSILON LECTURE

The second annual Phi Delta Epsilon medical lecture will be given at the University of Minnesota medical sciences amphitheater, at 8 P.M., November 3, 1948. The essayist is Franklin Hollander, Ph.D., head of the Gastroenterology Research Laboratory of Mount Sinai Hospital, New York City, on the subject "Studies in Gastric Secretion." The lecture is presented under the combined auspices of the University of Minnesota medical school, the Phi Delta Epsilon undergraduate fraternity and the Minnesota Phi Delta Epsilon graduate club.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

THE FOOT AND ANKLE; THEIR INJURIES, DISEASES, DEFORMITIES AND DISABILITIES. Philip Lewin, M.D., F.A.C.S., Associate Professor of Bone and Joint Surgery, and Acting Head of Department, Northwestern University Medical School; Professor of Orthopaedic Surgery, Post-Graduate Medical School of Cook County Hospital; Attending Orthopaedic Surgeon, Cook County Hospital; Senior Attending Orthopaedic Surgeon, Michael Reese Hospital; Consulting Orthopaedic Surgeon, Municipal Contagious Disease Hospital, Chicago; formerly Colonel, Medical Corps, AUS. 3rd ed. 847 pages. Illustrated. Philadelphia: Lea & Febiger, 1947. Price, $11.00.

The new edition of this exhaustive work has been revised to cover some of the experience gained in the recent war. In general, the same material is covered as in the preceding editions.

The work offers students and practitioners a comprehensive discussion of the lesions encountered in the lower extremities. The bibliography is extensive.

—S. W. SHIMONEK, M.D.

HANDBOOK OF OPHTHALMOLOGY. Everett L. Goar, A.B., M.D., F.A.C.S. Professor of Ophthalmology, Baylor University College of Medicine, Houston, Texas. 166 pages. Illus. Price $5.50, cloth. St. Louis: C. V. Mosby Co., 1948.

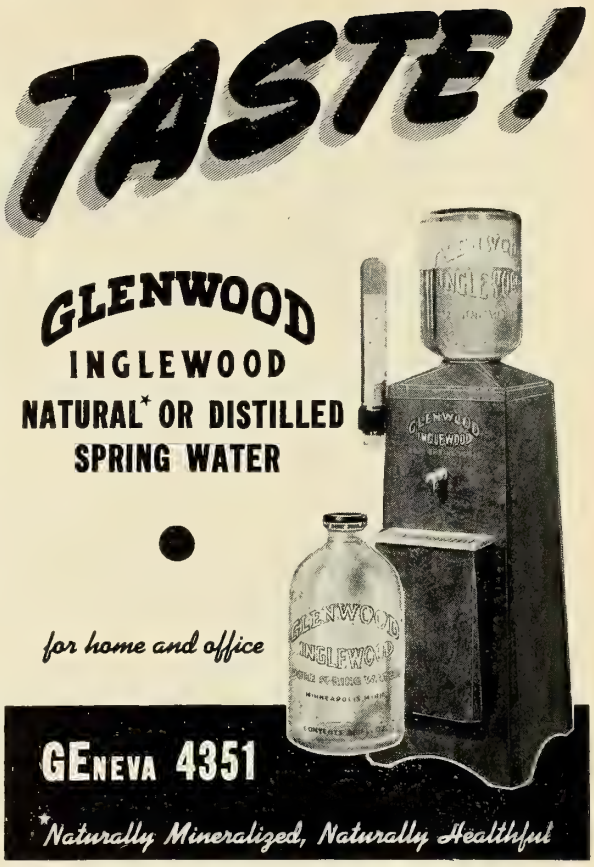
This volume is refreshing in its format, inasmuch as handbooks are usually small and the type likewise small. This book size is royal octavo and the type 11 point, and easy to read. There are 48 text illustrations and 7 color plates, all good.

The author occupies a high standing in this specialty of medicine and is best known to the members of the Academy of Ophthalmology and Otolaryngology for his proficiency in the teaching of Biomicroscopy.

He states in the preface that this treatise was first written as a series of lectures for the junior medical students and adds pertinently that the books then available contained too much material for them to grasp.

The subject matter is brought up to date, and the opinions expressed are authoritative.

The reviewer is impressed with the minimum of verbiage employed to include in such a thoroughgoing manner the basic knowledge of this wide subject.



This synopsis of ophthalmology should find an important place in the classrooms and libraries of the junior medical student.

The Nurses, Themselves, See It!

Miss Thelma Dodds, president of the Minnesota Nurses Association, at a meeting of the association in New York in July . . . .

"The shortage of nurses has reached a crisis and is virtually a threat to community health."

Substantially the same thing had been said by Miss Katherine J. Densford, director of the University of Minnesota school of nursing and a vice-president of the International Council of Nurses, the directors of which including Miss Densford, met in London last month.

10 Years Ago Glenwood Hills Hospitals saw the trend toward this acute condition, planned to meet it, set up a one-year course that is furnishing urban and rural hospitals, clinics and doctors with well trained, faithful, competent graduates. Doctors appreciate it.

These young women, with the prerequisite of high school education and the benefit of instruction in modern methods, modern nursing and modern patient care, particularly of psychiatric cases, are capable of appreciating the needs of that important person the patient, giving him the right attention and the right food to make him comfortable.

Thanks to you registered physicians, our midsummer class was oversubscribed. We are now enrolling for the January class in the

SCHOOL OF PSYCHIATRIC NURSING

Our graduates are the ones most desired by doctors and clinics. . . . They are well trained, loyal, eager to serve.

Doctors who operate their own hospitals in smaller communities seek our graduates.

The most capable of these graduates are the ones who come doctor-recommended.

We appreciate the cooperation rendered by you doctors

Nominate some young woman for the course.
We will send you and her our booklet.

SHOULD VITAMIN D BE GIVEN ONLY TO INFANTS?

VITAMIN D has been so successful in preventing rickets during infancy that there has been little emphasis on continuing its use after the second year.

But now a careful histologic study has been made which reveals a startlingly high incidence of rickets in children 2 to 14 years old. Follis, Jackson, Eliot, and Park* report that postmortem examination of 230 children of this age group showed the total prevalence of rickets to be 46.5%.

Rachitic changes were present as late as the fourteenth year, and the incidence was higher among children dying from acute disease than in those dying of chronic disease.

The authors conclude, "We doubt if slight degrees of rickets, such as we found in many of our children, interfere with health and development, but our studies as a whole afford reason to prolong administration of vitamin D to the age limit of our study, the fourteenth year, and especially indicate the necessity to suspect and to take the necessary measures to guard against rickets in sick children."

*R. H. Follis, D. Jackson, M. M. Eliot, and E. A. Park: Prevalence of rickets in children between two and fourteen years of age, Am. J. Dis. Child. 66:1-11, July 1943.

MEAD'S Oleum Percomorphum With Other Fish-Liver Oils and Viosterol is a potent source of vitamins A and D, which is well taken by older children because it can be given in small dosage or capsule form. This ease of administration favors continued year-round use, including periods of illness.
MEAD'S Oleum Percomorphum furnishes 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10- and 50-c.c. bottles and bottles of 50 and 250 capsules. Ethically marketed.

MEAD JOHNSON & COMPANY, Evansville 21, Ind., U.S.A.

Reliance on MAPHARSEN is reflected in its extensive clinical use—over 200,000,000 injections since 1940. The significant advantages of high therapeutic effectiveness and notable relative safety have established its value as an antispirochetal agent. Clinical and serological follow-ups continue to demonstrate its high percentage of cures. Equally adapted to intensive, intermediate or conventional prolonged treatment schedules, alone or with penicillin, MAPHARSEN is an arsenical of choice in the treatment of syphilis.

n MAPHARSEN®

an arsenical of choice

IN THE TREATMENT OF SYPHILIS

MAPHARSEN (oxophenarsine hydrochloride, P. D. & Co.) is supplied in single dose ampoules of 0.04 Gm. and 0.06 Gm., boxes of 10, and in multiple dose ampoules of 0.6 Gm. in boxes of 10.

PORTAL TO PORTAL INSURANCE

From the time the door closes at your office because of some sickness or accident, until it opens again, we pay you!

$25—$30—$40—$50 per week, according to the plan you choose.

When your office door closes, your bank book opens as you withdraw hard earned reserves to carry you through periods of disability. It's wisdom that suggests that you ask the insurance company to open their bank book in place of yours. It's logic that suggests you use your Minnesota State Medical Society's plan of accident and sickness insurance to insure your reserves soundly and inexpensively.

DO NOT DELAY—APPLY NOW.

for simultaneous

active immunization

DIPHTHERIA and TETANUS TOXOIDS

ALUM PRECIPITATED and

PERTUSSIS VACCINE COMBINED

SQUIBB

Among the many advantages of simultaneous immunization against diphtheria, tetanus and pertussis are:

- *Injections fewer and of smaller total volume*
- *Local and systemic reactions reduced to a minimum*
- *Greater convenience for physician and patient*
- *Less discomfort for the patient*

DIPHTHERIA and TETANUS TOXOIDS Alum Precipitated and PERTUSSIS VACCINE COMBINED SQUIBB is given in three injections of 0.5 cc. each at monthly intervals. This amount provides a full immunizing dose of both Diphtheria and Tetanus Toxoids and 45,000 million killed H. pertussis organisms.

In 1.5 cc. vials, providing 1 complete immunization.
In 7.5 cc. vials, providing 5 complete immunizations.

SQUIBB

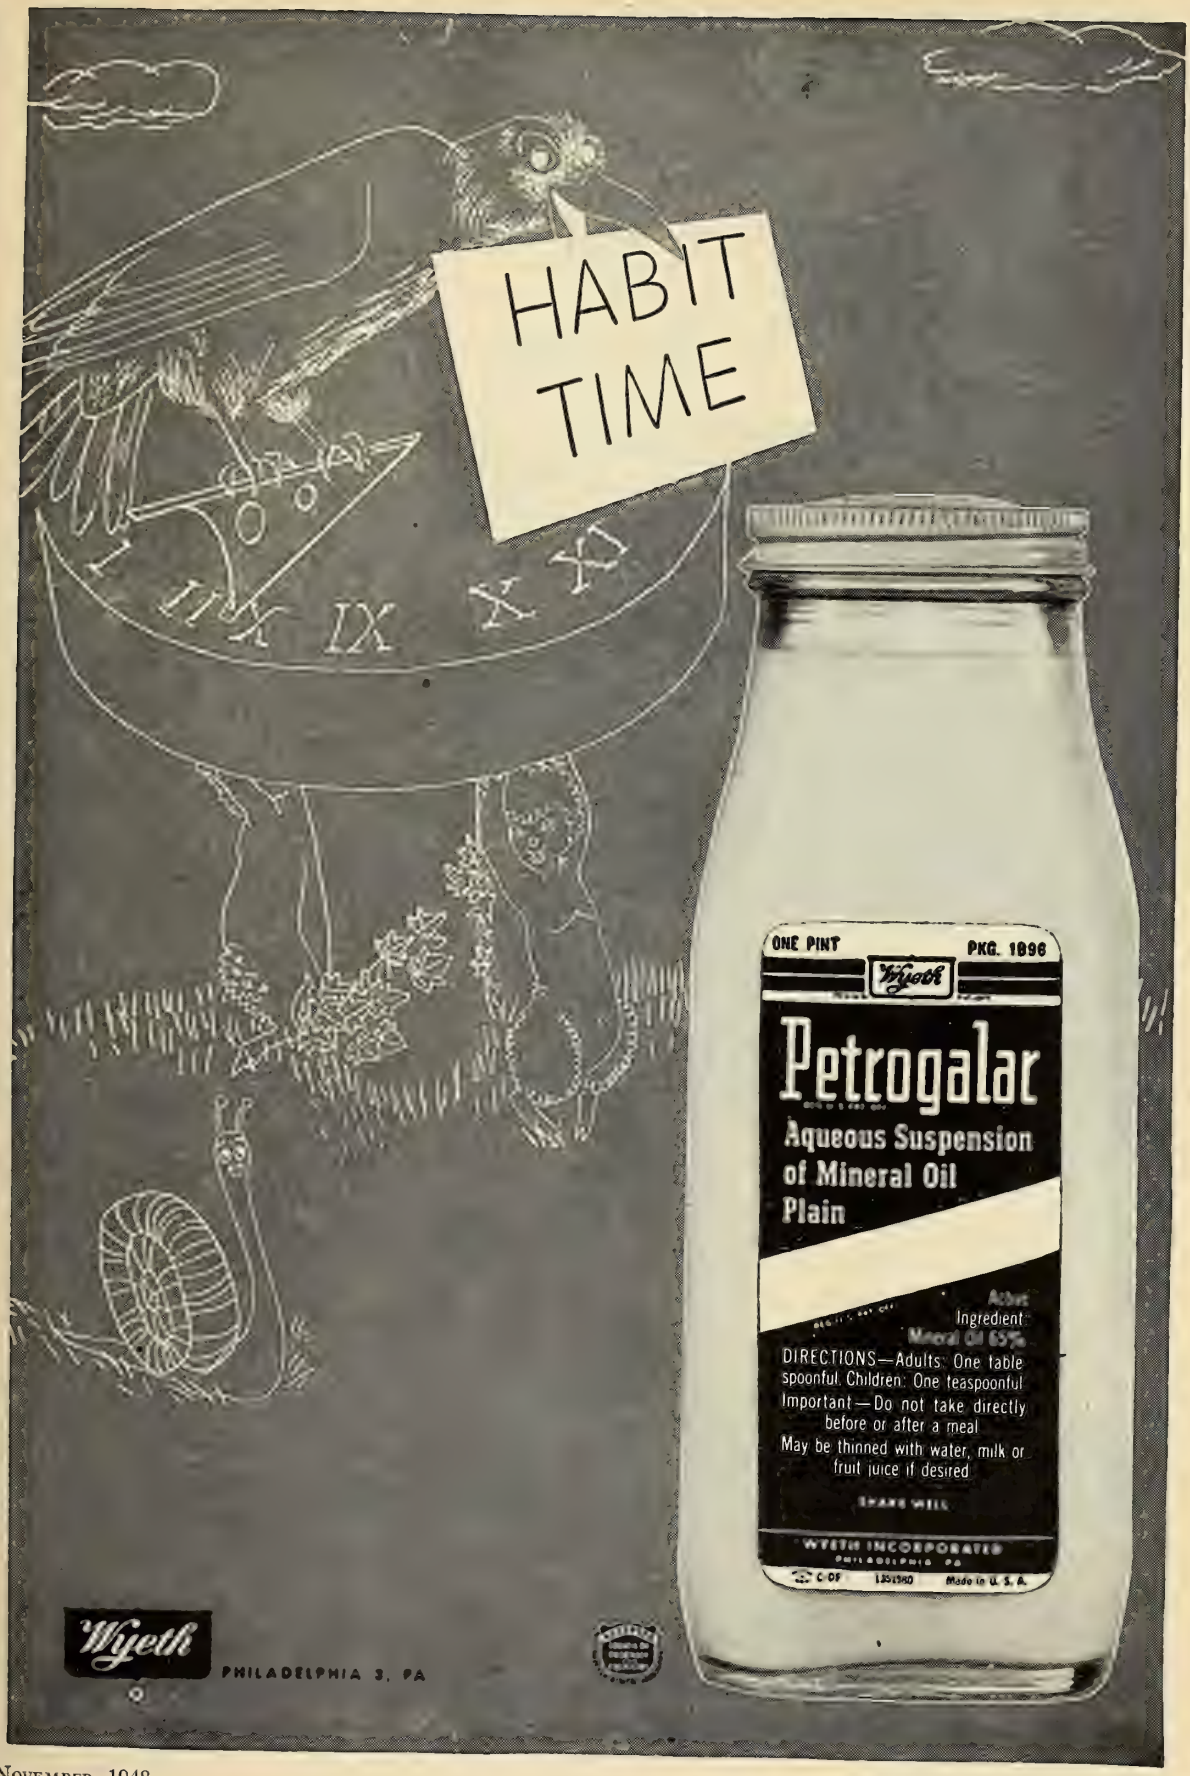
You'd never guess they're waiting for their vitamins—unless you are familiar with Abbott Vitamin Products. The oral forms are made as attractive as possible in appearance, odor and taste for the express purpose of encouraging patient adherence to the day-to-day doses you prescribe—an important factor with youngsters the country over, and with many finicky oldsters. ● These daily doses may be as potent as the patient requires, whether indications are for a diet supplement or for treatment of an acute deficiency. Among the many Abbott Vitamin Products you are sure to find one well suited to your patient's needs. Dosage forms are equally varied to meet individual requirements. Liquids, easily swallowed capsules and tablets, ampoules for parenteral use are all available through your pharmacy in single or multivitamin preparations.



All have the dependability, guaranteed potency and accurate standardization you expect in Abbott products.

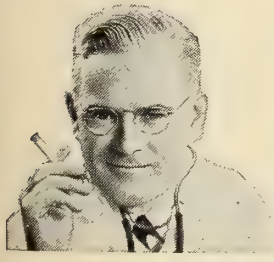
Experience is the Best Teacher



JOHN HUGHES BENNETT (1812-1875) proved it in histology

Bennett's experiences, gained by linking physiology with clinical medicine, led him to institute the practical study of histology, to recognize the medicinal value of cod liver oil, and to be the first to describe the blood condition leukemia—Bennett's disease.

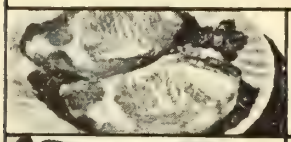
R. J. Reynolds Tobacco Company, Winston-Salem, N. C.

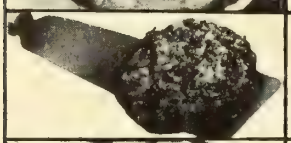
Experience is the best teacher in cigarettes, too!

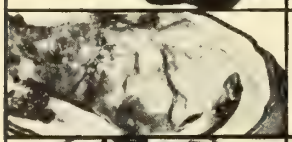
YES! Millions of smokers who have tried and compared many different brands of cigarettes found from experience that cool, full-flavored Camels suit them best.

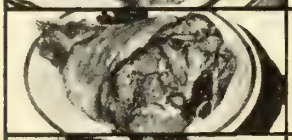
Try Camels! See how the full, rich flavor of Camel's choice, properly aged and expertly blended tobaccos pleases *your* taste. See if Camel's cool mildness isn't mighty welcome to your throat.

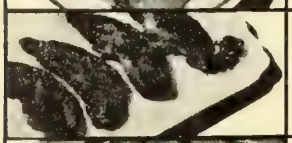
Yes! Let your taste and throat tell you why, with millions of smokers who have tried and compared, Camels are the "choice of experience."

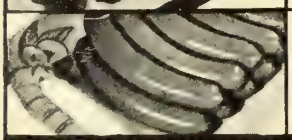












According to a Nationwide survey:

More Doctors Smoke CAMELS

than any other cigarette

In a nationwide survey by three independent research organizations, 113,597 doctors were asked to name the cigarette they smoked. More doctors named Camel than any other brand.

The Abundant Nutrient Values of MEAT

KIND OF MEAT	COMPLETE PROTEIN	B VITAMINS			FOOD IRON
		THIAMINE (B_1)	RIBOFLAVIN (B_2)	NIACIN	
 PORK	EXCELLENT	EXCELLENT	FAIR	EXCELLENT	EXCELLENT
 BEEF	EXCELLENT	FAIR	EXCELLENT	EXCELLENT	EXCELLENT
 LAMB	EXCELLENT	FAIR	GOOD	EXCELLENT	EXCELLENT
 VEAL	EXCELLENT	GOOD	GOOD	EXCELLENT	EXCELLENT
 VARIETY MEATS (LIVER, HEART, KIDNEY)	EXCELLENT	EXCELLENT	EXCELLENT	EXCELLENT	EXCELLENT
 SAUSAGE (FRANKFURTERS, BOLOGNA)	EXCELLENT	GOOD	GOOD	GOOD	EXCELLENT

ALL VALUES ARE BASED ON COOKED MEATS . . MEAT ALSO SUPPLIES SIGNIFICANT AMOUNTS OF COPPER AND PHOSPHORUS

While its high content of biologically complete protein ranks meat among man's best protein sources, its contribution of many more indispensable nutrients further enhances its over-all desirability in the daily dietary.

As is readily seen in the chart above, every kind of meat is an excellent source of high quality protein and of iron. Meat further supplies significant amounts of the three B complex vitamins, thiamine, riboflavin and niacin. Certain cuts and kinds of meat are, as a matter of fact, among our richest food sources of thiamine and niacin. All meat, regardless of grade or cut, makes these contributions.

Due to the excellent digestibility of meat—from 96 to 98 per cent—the metabolic availability of its protein and other nutrients is virtually assured, making it particularly valuable in many disease conditions in which these nutrients are especially needed.

Excellent results

IN ORAL ESTROGEN THERAPY

ESTINYL* (ethinyl estradiol) affords "relief of menopausal symptoms with excellent results"[1] in from 87.8 to 100 per cent[2] of cases. On a weight basis, ESTINYL is many times more powerful in estrogenic effect than other natural and synthetic estrogenic agents.[3] It acts rapidly, causing disappearance of hot flushes in 3 to 8 days[4] and often completely controls other climacteric symptoms in 7 to 10 days.[5]

ESTINYL

(ETHINYL ESTRADIOL)

is well tolerated, there usually being "complete absence of side reactions if minimal effective doses are administered."[2] An additional asset of ESTINYL therapy is the "sense of well-being"[6] it commonly evokes.

DOSAGE: One ESTINYL Tablet, 0.02 mg., or one teaspoonful of ESTINYL LIQUID daily. In severe cases two to three tablets daily, or their equivalent in ESTINYL LIQUID may be prescribed, reducing dosage as symptoms subside.

ESTINYL Tablets, 0.02 (buff) or 0.05 mg. (pink), in bottles of 100, 250 and 1000.

ESTINYL LIQUID, 0.03 mg. per 4 cc. (teaspoonful), in bottles of 4 and 16 oz.

Merck research has been directly responsible for many important contributions to the synthesis, development, and large-scale production of individual vitamin factors in pure form.

In a number of instances, the pure vitamins may be considered to be products of Merck research. Several were originally synthesized in The Merck Research Laboratories, and others have been synthesized by Merck chemists and collaborators in associated laboratories.

Merck experience in the production of vitamins extends from the time of the original synthesis of the first pure vitamin, down through the recent isolation of Vitamin B_{12} in The Merck Research Laboratories.

Because most of the known vitamins have now been made available in pure form, effective therapy of specific vitamin deficiencies can be conducted on a rational and controlled basis, under the direction of the physician.

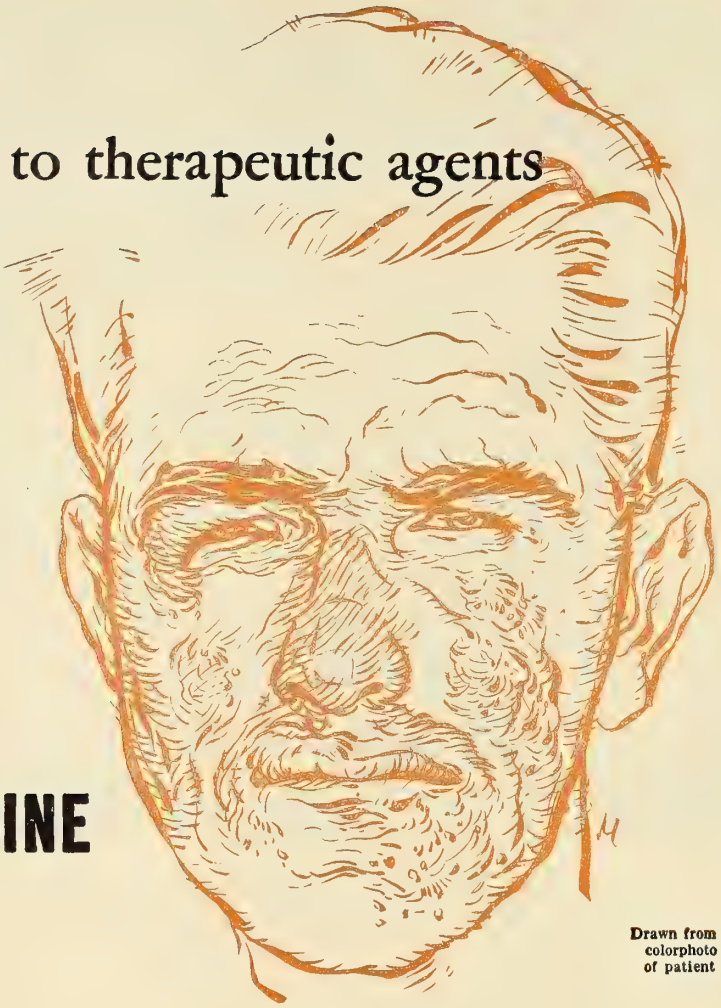
WHY MANY LEADING NOSE AND THROAT SPECIALISTS SUGGEST

"change to PHILIP MORRIS"*

Where smoking is a factor in a throat condition, the physician may advise "Don't Smoke." But where the patient persists, many eminent specialists suggest "*Change to* PHILIP MORRIS"... the *one* cigarette proved definitely less irritating.** Perhaps you too will find it advantageous to suggest to your throat patients "*Change to* PHILIP MORRIS." For your own smoking as well, Doctor, in fact for *all* smokers, Philip Morris is by far the wisest choice.

PHILIP MORRIS

Philip Morris & Co., Ltd., Inc.
119 Fifth Avenue, N. Y.



IF YOU SMOKE A PIPE... We suggest an unusually fine new blend—COUNTRY DOCTOR PIPE MIXTURE. Made by the same process as used in the manufacture of Philip Morris Cigarettes.

The First Antisepsis...

Medicine and Dentistry thank Joseph Lister (1827-1912) for discovering the principle of the prevention and cure of sepsis in wounds.

Convinced of a connection between Pasteur's bacteriological discoveries and his own perplexing quest for an answer to wound putrefaction, Lister in 1865 investigated a report that the town of Carlisle was solving its problem of sewage stench with carbolic acid. Returning to Glasgow, he made experiments proving that carbolic—plus clean, sterile hands, ligatures, etc.—effectively curbed surgery's traditional scourge, gangrene.

When Robert Koch showed in 1878 that wounds were not infected by bacteria from the air, Lord Lister's "donkey engine" and carbolic spray began to disappear from operating rooms. But his antiseptic principle prevailed . . . ending the era of soiled coats and blood-caked forceps . . . heralding the *sterile cleanliness* of modern medicine and dentistry.

Doctors Today, despite modern professional techniques and safeguards, still would have inadequate defense against the "surprise attacks" of malpractice allegations were it not for the *complete* protection, *preventive* counsel and *confidential* service assured them by their Medical Protective policies.

Milk

Cow's milk heads the list of "worst offenders" in infant diet allergies.[1,2] Obviously, "when one or more of the so-called essential foods are at fault, adequate substitutes must be provided if the symptoms are to be relieved and proper nutrition be maintained."[1] In all milk allergies (which may persist through infancy into childhood and even adulthood), MULL-SOY affords an ideal replacement. Completely free from offending animal proteins, it supplies a rich vegetable source of all the vital amino acids. Indeed, in standard dilution (1:1), MULL-SOY very closely resembles cow's milk in its percentages of protein, carbohydrate, fat and mineral content; and as a calcium source is comparable in every way with milk.[3] It is palatable, easily digested, and well-tolerated by every age.

MULL-SOY is a liquid hypoallergenic food prepared from water, soy flour, soy oil, dextrose, sucrose, calcium phosphate, calcium carbonate, salt, and soy lecithin; homogenized and sterilized. Available in 15½ fl. oz. cans at drugstores everywhere.

—and in later life, too...

THE TREATMENT OF OPEN WOUNDS OF THE HAND

MICHAEL L. MASON, M.D., F.A.C.S.

Chicago, Illinois

IT is essential that the surgeon caring for an injured hand know the general principles upon which treatment is based. He should know what he can or should do and what he cannot do. He should recognize that hand injuries are first priority injuries, that the patient cannot be put to bed and cared for in the morning, but must be cared for at the earliest possible moment. He should be guided by the axiom to save all viable tissue and should not feel obligated to perform extensive primary reparative surgery unless he is competent to do so and can anticipate primary healing. He should know that early secondary repair can be accomplished a few weeks after injury in a wound that has healed by first intention with almost as good results as following primary repair. He should keep in mind that secondary operations in wounds that have had disturbed healing are not only very difficult but must often be delayed for many months, entail long sessions of physical therapy, and frequently require multiple operative procedures to obtain often very mediocre results.

There are a few general principles upon which the surgical management of wounds of the hand is based. These principles are all rather interdependent and are premised on a concept of wound care from the standpoint of wound healing.

Primary Healing

Success in the management of wounds of the hand depends upon primary healing of the wound. Disturbances in healing greatly prolong the treatment and increase the disability. A minor infection will prolong the healing time from a normal of seven or ten days to three or four weeks, while a severe infection may prolong the healing many months, may lead to great tissue damage, and may threaten life. If a tendon repair has been done in such a wound, it is certain to be a failure, and secondary repair is not only very difficult but offers slight chance of success.

Asepsis

Strict asepsis must be maintained throughout all the care of the wound. In most wounds the invasive bacteria have been introduced into wounds after, rather than at, the time of injury. A few wounds, such as the human tooth injury, the autopsy knife and the safety pin from an infected case, introduce serious invasive contaminants, but as a rule, serious wound contaminants are introduced secondarily into a wound. In order to prevent this contamination we must know that the most common sources of invasive contaminants are the nose and throat of the patient, the first-aid man, the doctor, the nurse, or fellow patient. Other less frequent but nevertheless important sources are fingers, unsterile dressings and instruments. One source not often taken into account is the dust in wards and dressing rooms, particularly following a vigorous sweeping or the shaking out or folding of sheets and blankets. Shuffling about in operating and emergency rooms stirs up dust which may contain invasive bacteria.

The open wound should be covered as soon as

From the Department of Surgery, Northwestern University Medical School and the Passavant Memorial Hospital, Chicago, Illinois.

Read at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 7, 1948.

possible with a sterile dressing and not uncovered until it can be done under proper conditions, with all spectators, including the patient, masked. It should not be necessary to stress the need for proper sterilization of instruments and dressings which are used in wounds. One point that deserves stressing is the avoidance of touching or dressing wounds with the fingers, since, next to the nose and throat, fingers are the most potent carriers of virulent contaminants. Probing into wounds, even with a sterile probe, before the wound has been cleansed may carry bacteria into it from the surface.

Prevention of Further Trauma: Mechanical, Chemical, or Use

There are many kinds of trauma to which the wound or wounded part may be subjected. Use of the part disturbs healing, but we cannot simply tell the patient to keep the hand quiet. While the wounds may be well cared for as far as dressings and the initial operation are concerned, and all the newer remedies tried on it without success, seldom do we see a hand properly splinted, or even splinted at all. Starting with first aid, and throughout all care until satisfactory healing has taken place, putting the part at rest on a splint is an essential element of the care.

But the wound may be traumatized in other ways. For example, the wound may be filled with irritant chemicals in the hope of sterilizing it. This practice is both useless and harmful.

A wound is traumatized also by the mechanical act of operating upon it, and it is only by strict attention to operative technique that the surgeon can keep his operating trauma down to a minimum. Forceful retraction of tissues because of inadequate exposure is one of the most frequent sources of operative trauma. Tissues may be crushed in heavy forceps when they should be handled with the greatest gentleness to avoid irritating them. Very minimal operative trauma to tendons may lead to almost complete functional loss due to adhesions.

Early Care

Every wound of the hand should be cared for at the earliest possible moment.

Early care starts with first aid. Three very simple indications are to be met, and little elaborate equipment is needed. They are (1) to stop bleeding, (2) to cover the wound at once with a sterile dressing, and (3) to immobilize the hand. Practically all bleeding from wounds of the hand can be controlled by the pressure dressing and elevation. In a very few cases it will be necessary to apply a tourniquet. Too much emphasis has been placed in first-aid manuals on the tourniquet, which is often applied just tightly enough to cause venous congestion and increase the hemorrhage. The dressing should be large, not so that it simply will cover the wound, but to apply uniform resilient pressure over the whole wounded hand and lower forearm, to control hemorrhage and to help control the edema which is sure to occur. A large dressing tends to splint the hand and so helps to meet the third requirement of first aid, namely, to put the part at rest.

The injured hand should be splinted at once whether or not fractures are present, not only because the patient is much more comfortable, but because further injury is prevented thereby.

Once the patient reaches the doctor's office or the emergency room of the hospital he should receive care at the earliest possible moment. An open wound of the hand cannot be allowed to remain untreated overnight and added to the morning schedule. It is to be remembered that the usually accepted time limit for primary closure of wounds is six to eight hours, and for primary nerve and tendon repair is four hours, and that these limits, particularly the limits on nerve and tendon repair, are much shorter in some types of wounds. The longer the delay, the more likely the establishment of infection and increase of necrosis with resultant anerobic and aerobic saprophytic infestation.

Accurate Diagnosis

Accurate diagnosis of extent and nature of the injury is essential.

The surgeon should attempt to assess the full extent of the damage at the time the patient is first seen. The examination of the wound itself should be brief, and accomplished with patient and all examiners masked to avoid droplet contamination of the wound. Nerve and tendon damage can be diagnosed by examining for function of the various structures, and for this a few very simple tests are enough to indicate whether the median, ulnar or radial nerves or their branches have been divided. Tendon division can be detected by asking the patient to flex and extend

the different joints of the fingers and thumb and to move the wrist. For these tests it is usually not necessary to uncover the wound itself. The wound is uncovered briefly so that the surgeon can see where it is and know if some type of skin graft will be needed. An x-ray will always tell whether there has been a fracture.

A careful history of the wound from the time of its inception to the time the patient is received in the hospital is essential for intelligent care. When was the wound received? Here we are interested in the number of hours which have passed since the injury, and since an hour or two may determine whether or not we can perform primary closure, this information should be exact. What was the nature of the first-aid care? Have secondary contaminants been introduced into the wound by onlookers or others? Was the wound covered over at once or was it exposed for some time before being dressed? Was it covered with a sterile dressing or was an unclean cloth put over it? What was the nature of the injury itself? Was it due to a relatively clean object or to one which may have carried invasive organisms into the wound with it? What has been done with the wound since it was given first-aid care? Has it been probed or fingered? Has it been frequently uncovered and examined under doubtful conditions of asepsis? Have attempts been made to suture nerves and tendons in office or emergency room? All of the information thus gained will be of value to the surgeon in deciding on the manner in which he will treat the wound.

Has the patient other wounds which may require priority care? These wounds may be of such a nature that they endanger life, and the hand wound must either wait until they have been cared for, or extensive repairs must be foregone and planned on as secondary repairs at a later date.

The general condition of the patient should receive attention. Ordinarily, the patient with a wound of the hand only will not be in shock, but if other wounds are present, shock may develop and must be treated before the hand can be operated upon. If so, the necessary delay may change the surgeon's plan of procedure. Heart and lungs, blood and urine should be examined and the findings recorded. A wise precaution also is to ask the patient when he had his last meal. Hand wounds of any severity must usually be operated upon under a general anesthetic, and it is wise to empty a full stomach.

Surgically Clean Wound

The contaminated wound should be converted into a surgically clean wound.

A wound seen within a few hours can be converted into a clean wound at once; nerves and tendons can often be repaired and the wound can be closed primarily. If over four hours have elapsed, we can still cleanse the wound and, with proper excision, can close it. After eight hours have elapsed, it is unsafe to close most wounds, although we can perform a thorough cleansing and get it ready for secondary closure. If days have elapsed and severe secondary infection is present, the cleansing of the wound, the removal of necrotic tissue and the other steps making the wound ready for closure are much prolonged and may take weeks or months.

We do not pretend to get any wound bacteria-free. We hope, however, to remove from it the majority of the virulent invasive bacteria before they have had chance to multiply and invade. The tissues will usually take care of those left behind if we leave them in proper condition to do so. Chemicals and antibiotics will not compensate for carelessness in our cleansing of the wound.

Removal of wound contaminants and soiling may be accomplished either by excising all the contaminated tissue or by washing contaminants out. While wound excision would seem to be the ideal method of cleansing a wound, the surgeon seldom encounters a wound in which excision is at all feasible. A much simpler and more efficacious method of accomplishing the cleansing is available in simple soap and water washing of the wounds. This is a procedure which is applicable to all wounds and has been proven effective. The washing is done in a purposeful manner and is not just a matter of painting about the wound with soap and water. Each new group of residents, interns and clerks must be instructed carefully in the matter of washing wounds, and even after they have observed the technique several times, they still require supervision. The surgeon goes after it as if he really meant it. First covering up the wound with sterile dressings to protect it from the wash

water of the skin, he washes the surrounding skin for a full ten minutes, putting both thought and elbow grease into it. This washing is done with ordinary bar soap and sterile water, with soft cotton squares, not brushes, and for this reason we like to refer to the cleansing as washing and not as scrubbing, since that term connotes the use of a brush. The skin is rinsed, and the surgeon changes his rubber gloves and with another scrub set proceeds to wash out the wound itself with a generous amount of soap and water. After a full ten minutes of washing, the wound is rinsed with a large amount of sterile normal saline solution and is ready for draping.

Excision of Devitalized Tissues

Excision promotes healing by removing tissue which is destined to become necrotic. It is the removal not so much of bacteria as it is of bacterial food. Dead and devitalized tissue must be removed from the wound, if not at the time of primary care, then later either by the body tissues themselves or by bacterial decomposition. Surgeons are realizing more and more that the reason many wounds go "foul" is not simply because of the presence of virulent bacteria, but because of the presence of pabulum for organisms not primarily virulent but which thrive on products of tissue decomposition. Chemotherapeutic agents and the antibiotics will not take care of dead and dying tissue, and their use will not prevent the development of infection if nonviable tissue is left behind.

Wound excision need not be wide and radical; the surgeon is not attempting to remove the whole wound surface, only tissue destined to die. In the case of certain tissues, such as muscle and fat, the surgeon can be rather liberal; in case of tissue such as tendon, nerve and bone, he must be very conservative and remove only what is certainly destroyed or nonviable. Skin must not be needlessly sacrificed, but the surgeon should not leave avascular flaps to become gangrenous.

How are we to recognize devitalized tissues? Ordinarily, skin which is white, grey or purple is destined to succumb. Skin which looks like third degree burn skin is hopelessly injured. We can get some idea as to skin viability by considering the type of injury which has occurred. Clean-cutting wounds or sharply lacerated wounds will not produce much skin damage, while wounds due to severe crushes, abrasions and explosives must be very carefully considered since the skin may be so badly damaged that it cannot live. Wounds due to heavy weights falling on the part, even though the skin may look healthy at the start, are very productive of necrosis not only of the skin but of the deeper tissues as well. Gunshot wounds may not cause much damage to the skin even though the deeper tissues may be badly disrupted, and excision of a very narrow strip (a few millimeters) is sufficient. In the palm of the hand the surgeon must be very careful in his evaluation of the skin in case of injuries due to heavy weights falling on the hands, wounds due to machinery or other heavy objects moving across the palm, or falls in which the patient has slid for a distance on his palm. In such cases the epidermis will be seen to be lifted away from the underlying dermis, and the latter will have been torn and crushed severely without any external evidence of it. One or two days later, if the hand is examined, the thick epidermis will be found to be lifted up by a hemorrhage, and when this is removed a necrotic dermis will be found. These areas of skin damage must be excised at the start.

Flaps with pedicles distally are not likely to live unless they are very small. Flaps with pedicles proximally will usually survive if they are treated with a resilient pressure dressing to prevent congestion. The surgeon can gain some idea as to viability of flaps if he watches the return of circulation into them during the phase of active hyperemia after the blood pressure cuff has been released. Two things are to be watched for: a return of circulation as evidenced by reddening of the skin, and venous congestion as evidenced by a purple coloration. Skin which remains white following release of the cuff is avascular. The surgeon must wait a few minutes before making this decision since the circulation does not return at the same rate in all areas of the skin. Areas originally white will often show a slow return of reddish blush and finally come back satisfactorily. Skin which is dark and purplish after the initial blush may not be hopeless but may survive if the veins are properly supported by a compression dressing, and the surgeon can get some idea as to this by maintaining gentle pressure on the questionably viable skin for a few moments and watching its behavior. If under gentle pressure, which supports the venous return, the skin is pink and normal appearing, the surgeon can assume that

if this same resilient pressure is exerted by the postoperative dressings, the skin will survive.

Nonviable muscle is usually grey or greyish red; it does not contract and does not bleed. Here, again, the history of the injury is valuable, since with severe crushing wounds, muscle is likely to be devitalized. The surgeon can be fairly liberal in muscle excision if in doubt.

Fig. 1. Primary repair of extensor pollicis longus tendon. Wound was seen within one and a-half hours, cleansed with soap and water, irrigated with normal saline solution. Thumb was splinted in abduction and extension for five weeks following surgery. Primary healing. Result at end of seventh week.

Bone should be conserved if viable. Any bone fragments still attached to periosteum should be considered viable, but loose fragments should be removed.

Tendon should be submitted to a minimal excision. Ordinarily, only if severely crushed and shredded, should it be excised. Certainly the clean cut ends of tendons in sharply lacerated wounds can usually be left alone. Over the dorsum of the hand in crushing wounds, the extensor tendons are likely to be badly torn and frayed, but even here any healthy looking shreds should be saved if they can be used to conserve continuity. Nerve, likewise, should not be excised. Nerve is remarkably viable even if it is badly frayed.

Extent of Primary Repair

The extent of primary repair permissible in the open wound should be determined.

After the surgeon has properly cleansed the wound and has excised nonviable tissues, he should decide on the amount of surgical repair to be done. To reach this decision he must ask himself several questions. The first is: Can primary healing of the wound be expected? If the wound can be expected to heal by primary intention, extensive nerve and tendon repair may be done; if such healing cannot be anticipated, then deep repair must be postponed until a later date, and undertaken as a secondary operation under more favorable conditions.

The decision to perform deep repair will depend also on the nature of the wound itself. Sharply cut wounds, such as are produced by broken glass, knives, tin cans, et cetera, do not cause a great amount of tissue damage beyond the actual tissue division. On the other hand, some lacerated wounds due to heavy jagged edges of stones, punch presses, et cetera, cause considerable damage to the edge of the wound; the divided structures are likely to be macerated and torn, the tissues disrupted and often avulsed. In wounds of this type a fair amount of excision will be required to remove the nonviable tissues, and those viable tissues left are often far from normal and may not be suitable for primary repair. In wounds of this nature, the surgeon should usually refrain from immediate nerve and tendon repair.

Crushing injuries and wounds associated with compound fractures and joint injuries, and wounds with such loss of covering tissues as to require skin grafts for closure are not suitable for tendon repair. A tendon sutured over the site of a compound fracture is certain to become densely adherent to the bone callus and a secondary operation will undoubtedly be required.

Can the wound be completely closed with a satisfactory layer of skin and subcutaneous tissue over the site of nerve and tendon repair? If the wound cannot be closed because of the probability of serious contamination, or because it has been received too late to permit closure, nerve and ten-

don repair are out of the question. If it is necessary to use some type of graft to close the wound, nerve and tendon repair are also precluded unless the grafts are laid on some spot away from the actual site of suture. While split grafts will take over bone and tendon if there is a thin layer of areolar tissue between them and the graft, we cannot place grafts over a sutured tendon or over the site of nerve suture, or over bare bone with any chance of success. Occasionally it is possible to shift a flap of skin in such a way as to cover the site of a tendon repair and to cover the defect left by shifting of skin with a split graft.

There are several other general considerations which should go through the surgeon's mind when he attempts to decide on the extent to which a wound should be repaired as a primary procedure.

He should have adequate assistance if extensive repairs are to be undertaken. Without skilled help, the man who tries to repair a number of tendons in the wrist or fingers, or to close a complicated wound after delicate deep repair, finds himself in more and more difficulty. A competent anesthetist is needed to carry the patient through a long operation with safety, since these operations can seldom be done under local anesthesia.

The surgeon must not be rushed but must take all the time needed to finish a long and difficult task. If he is not willing to take all the time needed to do the job correctly, then both he and the patient are better off if the repair be skipped and a secondary repair done later under less trying circumstances.

The surgeon should know how to perform the technical steps necessary to repair nerve and tendon. If not, he should not attempt them, but simply close the wound, since an incorrect technical repair is not only bound to be unsuccessful but also makes the secondary operation very much more difficult, if not impossible.

The surgeon who does nerve and tendon repair should be acquainted with the proper after-care for these operations. He should know how to splint the hand, how long to leave the splint on, and how to start motion in different types of tendon repair and for support of the small muscles paralyzed by nerve division. He should be willing to watch the patient through the long months often necessary for recovery and know how to judge the course of recovery. While many of these considerations may not loom very large when the case presents itself and in the first few weeks after operation, they become increasingly important as time wears on—particularly important if too early use leads to separation of a tendon which had been moving a finger quite well until a slight force was exerted—important if the question of nerve regeneration leads to doubt as to whether or not a proper suture had been performed.

A few specific considerations may be discussed as to primary tendon, nerve and bone repair.

Time since injury is a most important consideration in determining whether or not to perform a tendon suture. It may be taken as a strict rule never to do a primary suture of tendons in wounds over four hours old, and this upper limit is to be taken only in clean-cut incised wounds. In the case of tendons divided in the digital sheaths, the absolute upper limit within which it is permissible to perform a primary suture is two hours, and then only in cleanly cut wounds, e.g., test tube or burette lacerations, milk bottle cuts, et cetera. Where these time limits are overstepped, the general wound therapy is carried out, closure is accomplished if indicated, and the tendon repair postponed until a later date.

Where primary tendon repair is indicated, all tendons are carefully sutured individually. Where the profundus and sublimis tendons have been cut within the finger (usually at the base of the proximal phalanx), only the profundus is sutured and the sublimis slips are excised. If both tendons are repaired, there are produced three tendon calluses which become adherent to each other, and to the phalanges as well, so that poor or no function results. When suture is accomplished in the fingers, it is essential to excise a window from the fibrous sheath overlying the site of repair so that the healing tendon lies in contact with soft well-vascularized subcutaneous tissue from which it can obtain a good blood supply during its healing period. If the blood supply is obtained from the fibrous tendon sheath, the healing tendon will become adherent to dense fibrous tissue.

There are a number of methods devised for the suturing of tendons. As long as they follow certain principles they will be successful. To secure end-to-end union, the tendon ends should be opposed accurately, and no foreign matter, suture

or blood clot should lie between them. The opposed ends of the tendon, which are playing a very important part in the process of repair, should be as free of suture material as possible so as to leave the proliferating ends free. In very occasional cases a side-to-side suture of tendon may be done, but not often without the danger of producing shortening and a bulbous adherent line of union. Hence, an end-to-end suture is most often used.

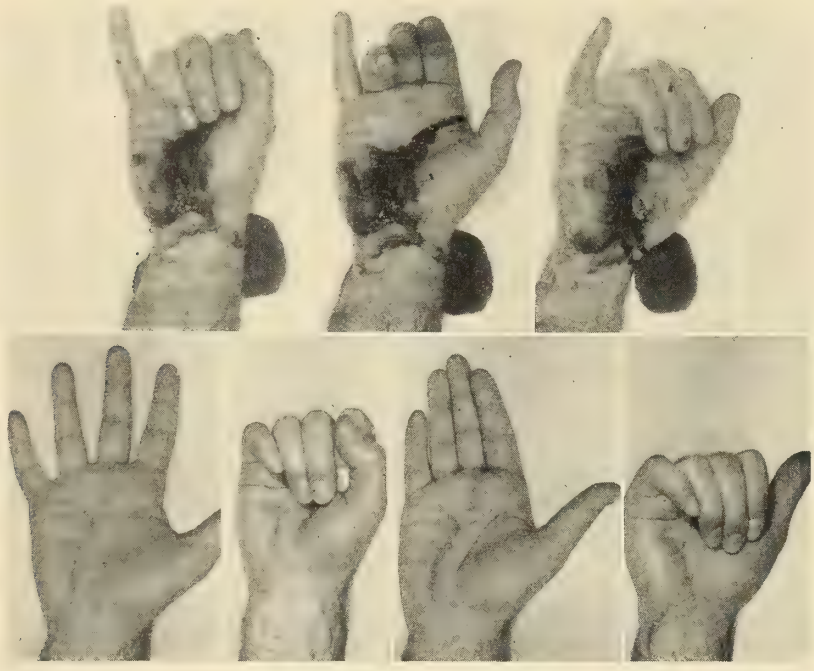

Fig. 2. Primary repair of flexor tendons of fifth finger and of sensory branches of ulnar nerve two hours after injury. It was necessary to enlarge the wound in the palm by a curved distal incision, and to prolong the proximal end of the wound across the wrist by a curving incision toward the ulnar side. Primary healing. Splinted to relax the sutured nerve and tendons for three and a half weeks. Result at end of two months.

Just as there are various methods used to secure tendon suture, so there are various materials used for sutures. As requisites for tendon suture material we may specify fine diameter, tensile strength of about 4 to 5 pounds, and relative nonirritability in the tissues. Catgut, although occasionally used by the general surgeon who attempts a tendon suture, has been given up by men who have had experience with this type of work. The three materials which are most used today are silk, cotton and stainless steel wire. These three are all practically nonirritant to the tendon and possess very satisfactory tensile strength in their finer grades. My own preference is for silk of the untreated variety, since I feel that any substance added to silk is very likely to be irritant. Silk is preferable to cotton, since it seems to me to be somewhat smaller, strength for strength, than cotton, and there seems to be very little difference in irritant properties between the two. Steel is a bit difficult to handle, and there is always the danger of puncturing the gloves. It seems to be the least irritant of the three, but to my mind this quality is overweighed by the difficulties of handling.

The technique of suture which has proved successful in our hands is one in which the suture pulls transversely across the tendon, and then turning at a right angle across the knot of another suture, pulls in the long axis of the tendon. These appositional sutures are paired, two being introduced into each of the stumps about 1.5 cm. from the cut end, and are tied to each other on the outside of the tendon. The ends are then accurately opposed by means of several very fine silk sutures which pass through the sheath only.

It is important in repairing tendons to leave retaining ligaments sufficiently intact to prevent bow stringing. The transverse carpal ligament, if it has been divided, should be repaired at the

end of the operation. While doing the repair of tendons in the fingers, it has been advised to cut out a window in the sheath. This window does not destroy the retaining apparatus of the finger tendons but leaves the sheaths intact above and below, and bowstringing does not take place. To be avoided is the complete division of the fibrous tendon sheath in the finger since if this is done, the repaired tendon will pull forwards and a serious functional disturbance will follow.

A few specific details of indications and technique apply to the problem of nerve suture. As far as the time interval between injury and repair is concerned, it is my feeling that nerves may be safely sutured up to the time limit within which the wound may be closed. If the wound is seen too late to permit primary closure, then it is probably not wise to attempt nerve repair, although it may be permissible to place a single suture through the perineurium of the two ends and to bring them together loosely to prevent separation.

There is some discussion today as to the advisability of performing primary nerve repair at all. Some surgeons believe that because of the softness of the freshly divided nerve ends and the great difficulties experienced in performing a primary suture, it is much better to wait until the wound has healed and to perform a secondary suture by choice. At the time of secondary repair the ends will be found to be slightly fibrosed and more easily handled; it will be possible at that time to determine the extent of nerve damage by slicing the nerve stumps until normal cross sections are obtained. It is pointed out that at first it is not always easy to determine the extent of nerve damage because of the disruption by the injury. At time of secondary repair it is said, however, the extent of damage can be accurately determined. I cannot agree with this position, granting the greater technical ease of secondary repair. Restoration of continuity at the time of primary operation offers the best chances for nerve regeneration and avoidance of trophic changes which are sure to occur if the ends are not united. If nerve suture is permissible, primary suture is the procedure of choice.

Recognition of nerves in the primary wound may be difficult because of the suffusion of blood into and about them. The surgeon will save time if he goes above and below the site of injury to seek for the nerve in normal tissues and under normal relations, and then traces it to the site of the wound. Nerve should not be confused with tendon if a few distinguishing characteristics are kept in mind. The vascularity of nerve gives the clue to its identity, for whereas tendon is white and glistening and almost homogeneous on first glance, nerve is pink and striated, and soft. Often a vessel can be seen coursing over the surface of the nerve. In case of the median nerve this is invariably present and may be a very sizable artery.

Hemostasis in case of nerves must be perfect, since if a clot comes between the ends, it forms an almost certain barrier to the downgrowth of axones.

The opposition of the nerve ends must be perfect so as to leave no gap which will fill up with clots and serum. The ends must match as closely as possible so that corresponding nerve bundles are opposed. This is not always easy in wounds in which there has been great disruption of tissues, and the nerve ends have been dislocated. In clean-cut wounds, however, the surgeon can often orient the nerves by placing a fine silk suture through the perineurium of each stump before mobilizing it, marking corresponding points on each stump. Some clue as to matching bundles is gained from an inspection of the cut ends. Where there has been a large gap between the stumps, the bundles may no longer correspond, and in such instances the best guide to correct alignment is to place the nerve in its anatomic position and see how "it wants to lie" and suture it in that alignment.

It should not be necessary to caution gentleness in handling the nerve ends, to avoid crushing them or grasping them in forceps. Suturing should be done with the finest of silk. We prefer 7-0 ophthalmic silk swaged on very fine needles. The sutures must pass only through the perineurium and *not* through the substance of the nerve. A number of sutures are necessary: eight to twelve on a median or ulnar nerve, three to four on a digital nerve.

The suture line must be placed in a position where it is not involved in scar or becomes attached to callus or healing tendons. It is usually possible to place the sutured nerve in a bed of fat or muscle.

There is still some discussion as to the need

THE MANAGEMENT OF VASOMOTOR RHINITIS

HADDON M. CARRYER, M.D., and CLIFFORD F. LAKE, M.D.
Rochester, Minnesota

PATIENTS with vasomotor rhinitis present a vexing problem which not infrequently is difficult to solve. The reasons for the trouble in the management of this condition lie for the most part in the fact that this disease is, as yet, incompletely understood. In all probability, vasomotor rhinitis represents a group of conditions which have similar symptoms. Although in a broad interpretation, vasomotor rhinitis is included in the group of allergic diseases, many factors not directly resulting from hypersensitivity may be of major importance in its causation. In vasomotor rhinitis in which contact with allergens is of most importance, nonallergic factors play secondary but nevertheless important roles. At times, vasomotor rhinitis appears to arise solely from factors present within the body.

Although uncomplicated vasomotor rhinitis is not a serious disease, the problems of social adjustment which sufferers from it present may make the disability a major one. Diseases secondary to vasomotor rhinitis, particularly chronic infections of the paranasal sinuses, also frequently give trouble.

The symptoms of uncomplicated vasomotor rhinitis are most commonly intermittent. They often assume a diurnal pattern of exacerbations and remissions regardless of contact with offending substances. Symptoms are likely to be more severe in the morning and to reach their greatest severity at about the time the patient rises. After a stormy phase which may last minutes to several hours, the symptoms gradually abate and the patient is relatively comfortable. Some patients experience a less pronounced return of symptoms in late afternoon, particularly with fatigue.

Nasal congestion, with associated decrease in breathing space within the nose, is the most common complaint offered. Usually there is some nasal drainage which may be one of two types. Most characteristic is a watery secretion from the anterior part of the nose which may drip from the nose if the patient flexes his head. The other type consists of more than a physiologic amount of postnasal drainage of mucoid material. This type of nasal drainage characteristically occurs between the acute paroxysms of nasal congestion. Sneezing is usually, although not necessarily, associated with vasomotor rhinitis. Patients who have nasal allergic disease sneeze many times in quick succession, whereas those who have a common cold rarely sneeze more than three times. This observation is a point of diagnostic value. An intense sensation of itching in the conjunctiva, palate and ears often occurs in extrinsic vasomotor rhinitis. Discomfort in the region of the paranasal sinuses frequently is observed by patients during paroxysms of vasomotor rhinitis.

The symptoms of vasomotor rhinitis gradually become more persistent if polypoid degeneration of the nasal mucosa develops. Not infrequently interference with drainage of the paranasal sinuses leads to retention of secretion and is followed by chronic infection of these cavities.

The pathologic changes associated with vasomotor rhinitis vary with the severity and the duration of the condition. Grossly the mucous membrane becomes boggy, pale and somewhat bluish. In cases of longer duration, polyps may develop. The nasal secretion in allergic vasomotor rhinitis contains a considerable number of eosinophilic leukocytes, and this finding is a point of diagnostic importance. In cases in which chronic sinusitis has developed, purulent secretion may be observed, usually in the middle meatus of the nose or on the posterior pharyngeal wall. Nasal secretion contains no reducing substance; this characteristic of nasal secretion is of value in differentiating the drainage of vasomotor rhinitis from cerebrospinal rhinorrhea. When the patient presents a history of meningitis or of severe injury to the head, the possibility of cerebrospinal rhinorrhea should be considered. Cerebrospinal rhinorrhea may occur spontaneously and is suggested in those instances wherein unilateral drainage occurs. All known factors contributing to vasomotor rhinitis should be considered and their roles evaluated in each case. It has been found helpful to approach the treatment of vasomotor rhinitis with a consideration of the etiologic fac-

Dr. Carryer is with the Division of Medicine and Dr. Lake is with the Section on Otorhinolaryngology of the Mayo Clinic, Rochester, Minnesota.

tors and complications. These are listed in the following outline.

1. Etiologic factors.
   (A) Allergic factors.
   (B) Physical allergic factors.
      (1) Exaggerated nasal responses to normal stimuli.
      (2) Exaggerated nasal responses to increased stimuli, usually occupational.
   (C) Neurogenic factors.
   (D) Endocrine factors.
      (1) Hypothyroidism.
      (2) Pregnancy.
      (3) Menopause.
   (E) Chronic nasal irritation.
      (1) Physical irritants.
      (2) Chemical irritants.
      (3) Infections.
         (a) Chronic sinusitis.
         (b) Acute respiratory infections
   (F) Intranasal structural abnormalities.
2. Complications of vasomotor rhinitis.
   (A) Chronic sinusitis.
   (B) Polypoid degeneration.
   (C) Vasodilating pain syndrome.

A brief description of the diagnostic factors and special features in the management of vasomotor rhinitis, due to various etiologic factors, and of the complications will be given. Then certain specific therapeutic procedures will be considered.

Allergic Factors

In an evaluation of the allergic factors in vasomotor rhinitis, several criteria may be considered. The age at which this disease appears is significant. True allergic vasomotor rhinitis most commonly appears before the patient is forty years old. Vasomotor rhinitis in younger individuals does not always indicate the presence of a specific allergic factor; nevertheless, in most instances there is one. The occurrence of allergic diseases in other members of the family, or the coexistence of other manifestations of allergy in the patient, is suggestive of an extrinsic causation for vasomotor rhinitis. Patients in families presenting allergic diatheses are more subject, however, to vasomotor rhinitis of both allergic and other types.

An allergic survey should be undertaken, and skin tests should be made with common allergens with which the patient may come into contact. It is good practice to include at least the inhalant and ingestant allergens shown in the accompanying list in such a survey.

In addition to these substances, the occupational, recreational, domestic and dietary allergens that the patient may encounter should be considered and the necessary tests made. It is well also to evaluate the role of miscellaneous substances, such as cottonseed, flaxseed, karaya, molds and wool, in causing the disease. We have largely excluded from consideration in this presentation the testing of patients for seasonal symptoms resulting from pollinosis.

Sensitivity to the substances among the inhalants should be tested by the intracutaneous method. When pollens are in the atmosphere or when the patient is known to have pollinosis, the pollen extracts are best omitted from the group of allergens tested intracutaneously, inasmuch as the small amount of an extract of a pollen injected into the skin may evoke an untoward response. For children for whom intracutaneous testing may prove objectionable, scratch or passive transfer skin testing may be substituted.

Inhalants	*Ingestants*
Mixed ragweed	Buckwheat
Orris root	Corn
Timothy	Oats
Cat hair	Rice
Cattle hair	Rye
Dog hair	Whole wheat
Goat hair	Whole egg
Horse hair	Beef
Rabbit hair	Chicken
Chicken feathers	Pork
Duck feathers	Lamb
Goose feathers	Cocoa
House dust	Whole milk
Kapok	Orange
Pyrethrum	Peanut
	Potato

Sensitivity to the substances among the ingestants is best determined by the scratch method. Equivocal results may be re-evaluated by intracutaneous testing if this should appear to be warranted. When the history is negative for trouble following ingestion of substances contained in this group, tests may be omitted for most patients who first develop nasal disease at an age past forty years.

Instructions in the avoidance of substances yielding positive reactions on skin tests should be outlined definitely in the case of inhalant allergens and should be considered in the case of ingested allergens.

In most cases in which there is an allergic factor, a plan for a dust-free bedroom should be provided. The preparation of such a room should include the removal of rugs, overstuffed furniture, drapes, the contents of closets and all other common sources of dust. Covers impervious to dust should be applied to both the pillow and

mattress. If there are two beds in the room, both should be prepared in this manner. Feather ticks and down comforters should be discarded. Woolen bedclothes devoid of lint may be used, and a generous fold of sheet should be placed over the upper portion of the blankets. Changing and storage of clothing should be done outside this room. Small animals should be kept from the room. Steam or hot-water heat is preferable to hot-air heat. If hot-air vents are in the room, filters of dust-proof fabrics should be provided for these. This room should be cleaned daily with a damp cloth rather than by sweeping or by a dust mop. Should the patient be a child, it is unwise to allow the use of stuffed or fur-trimmed toys.

When the avoidance of contact with an offending inhalant allergen is impossible, the advisability of specific desensitization should be considered. Results from desensitization are less favorable than one might wish. When results are good, the benefit sustained is frequently transient. Scrupulous avoidance of offending allergens remains the most effective form of therapy.

With regard to ingestion of allergens, it is possible that the conscientious patient may place too much emphasis on the problem, since it is uncommon for food to be of major importance in the etiology of vasomotor rhinitis which begins after the fourth decade of life. In use of diets designed to exclude offending foods, it must be remembered that no diet should allow the patient's nutrition to suffer. Brief trial periods of no greater duration than one month usually suffice to answer a physician's question concerning the role of ingested allergens. The occurrence of a positive reaction to a skin test is, in itself, insufficient evidence to omit from a diet nutritious foods known clinically to be tolerated. Through use of bizarre and inadequate diets, many patients will cause their health to suffer more than it would from the atopic disorders prompting the use of such diets.

Physical Allergic Factors

The role of "physical allergy," which usually means hypersensitivity of the patient to changes in temperature and the cooling effect of moving air, recently has been emphasized in vasomotor rhinitis.[6] Patients exhibiting this disturbance have grown extremely sensitive to such stimuli as wide variation in their environmental temperature, the moving air from fans, ventilating devices and air-conditioning systems, or contact of the skin with cold objects. Brief exposures to such stimuli will serve to evoke a response in the nasal mucosa far greater than the minimal physiologic responses noted in the great majority of individuals. The relationship between vasomotor rhinitis resulting from physical allergy and that from other etiologic factors is probably a close one. Patients with an essentially allergic vasomotor rhinitis often will exhibit an exaggerated sensitivity to the changes in temperature of their environment.

Patients who have physical allergy can be classed into two groups. The larger group consists of patients whose nasal responses are exaggerated to the usual changes in temperature which are well tolerated by most normal individuals. The smaller group is comprised of persons who are affected by wide variations of temperature or excessive movement of air encountered in their occupations. In this group are included butchers, florists, dairy workers, grocers, gas station attendants and others whose activities or occupations necessitate their frequent entrance into ice-boxes, refrigerated rooms or frequent passage in and out of doors. In such patients the nasal reflex responses may be normal to the usual stimuli but are exaggerated to occupational stimuli of greater degree.

Patients in both groups should strive to live in a constant environmental temperature in an atmosphere which is devoid of drafts. Rooms should be adequately humidified and heated without excessive movement of air from ventilating systems. At night the windows should be kept closed in order that the temperature may be maintained at 65° F. or more. The bed, chairs, desks and parts of the house frequented by the patient should be arranged so that he can avoid cross ventilation. Care should be exercised to minimize as much as possible the necessity for entering air-conditioned buildings and theaters. Adequately warm dress should be encouraged. Minor changes in routine followed in the course of an occupation may greatly lessen contact with the objectionable factors listed.

Neurogenic Factor

The neurogenic factor is a major contributing cause in the production of nasal symptoms of many patients. The responses observed in vasomotor rhinitis result from a reflex mechanism,

and their severity may be appreciably altered by the emotional state. Therapy directed toward the correction of any underlying nervous tension frequently will decrease the severity of nasal symptoms. Likewise, it is apparent that the patient's ability to tolerate discomfort of constant degree will be appreciably diminished by a tension state.

Endocrine Factors

Nasal changes characteristic of vasomotor rhinitis are observed in the course of certain endocrine disturbances. Lillie and Haines[4] called attention to such a disturbance among patients who have excessively low metabolic rates but do not have myxedema. An elevation of the metabolic rate in such cases is often associated with a regression of nasal symptoms. Vasomotor rhinitis likewise is at times a troublesome complication of pregnancy. Termination of the pregnancy through parturition often brings remission of the symptoms. Women experiencing vasomotor instability associated with the menopause will at times find a paroxysm of vasomotor rhinitis beginning with the flushes. Treatment with estrogenic substances is of value in such instances.

Chronic Nasal Irritation

Even in the absence of definite evidence of sensitivity, patients who have vasomotor rhinitis should exercise every precaution to avoid contact with physically irritating substances which might further aggravate their nasal condition. The use of a dust-free bedroom, the disposal of rug pads, and adequate slip covering or disposal of overstuffed furniture will serve to minimize common sources of nasal irritation.

Certain physically irritating habits may develop. Habits of sniffing, hard blowing, hacking and other objectionable practices into which the victim of vasomotor rhinitis may fall should be discouraged.

Likewise, chemical irritants should be avoided if everything therapeutically is to be done to control the vasomotor rhinitis. Tobacco smoke, occupational fumes and contact with heavily scented objects frequently will initiate a paroxysm of nasal congestion or sneezing. To be discouraged is the practice of self-medication by nose drops, sprays and irrigations.[3] Although many of these astringent solutions will shrink the nasal membranes for brief periods, the irritation they provoke in so doing serves only to aggravate ultimately the chronic nasal disease.

The drainage of secretions from the paranasal sinuses is impaired by mucosal edema during a paroxysm of vasomotor rhinitis. Polypoid degeneration of the nasal mucous membrane likewise will disturb adequate drainage of the sinuses, thus tending to bring about a chronic infection in these chambers. Conversely, the constant seepage of irritating and infectious exudates serves to perpetuate the changes noted in vasomotor rhinitis. Should other measures in the management of vasomotor rhinitis fail to bring about regression in the size of polypoid tissue and fail to produce sufficient drainage to allow subsidence of chronic sinusitis, intranasal surgical procedures may be warranted. The use of radium to effect a subepithelial fibrosis after polypectomy helps to prevent recurrence of the polyps. Radium applied to lymphoid structures in the nasopharynx is at times valuable in securing adequate drainage from the paranasal sinuses. A transient type of vasomotor rhinitis at times is observed for days to weeks after upper respiratory infections.

Intranasal Abnormalities

A widely deflected nasal septum, nasal spur or markedly hypertrophied nasal turbinates through contact with other intranasal structures may reflexly initiate changes in the nasal mucous membrane which are characteristic of vasomotor rhinitis. The surgical correction of such structural abnormalities in the treatment of vasomotor rhinitis should be deferred until more conservative methods of therapy have proved ineffectual. Before each surgical procedure is undertaken, its probable benefit should be weighed carefully against the disturbance of intranasal physiologic processes which may follow the operation.

Complications

In addition to the polypoid degeneration and chronic inflammatory changes so often observed consequent to vasomotor rhinitis, which were mentioned under chronic irritation, there is a third complication, the vasodilating pain syndrome.[7] Often patients who have this complication complain bitterly of discomfort in the region of the nasal accessory sinuses, but no active inflammatory changes are evident within the sinuses. At times, fatigue or tension serves to aggravate the severity of symptoms of "stuffiness" or "fullness"

which occur in the course of vasomotor rhinitis. When pain about the face is the presenting symptom, care should be exercised to exclude an underlying though minimal vasomotor rhinitis as an etiologic factor. At times vasomotor rhinitis will serve to initiate pain of the so-called sphenopalatine ganglion syndrome wherein the reference of pain extends from the region of the eye to the ear and into the neck.[5]

Specific Treatment

The number of specific forms of therapy for vasomotor rhinitis recommended in the literature suggests the situation existing in the pre-insulin era of diabetes mellitus. No one form of treatment has been spectacularly successful to the exclusion of other procedures. There are, however, a number of useful procedures which deserve consideration because of their advantage in selected cases.

The recent advent of drugs manifesting antihistaminic properties represents an advance in the treatment of vasomotor rhinitis. The use of β-dimethylaminoethyl benzhydryl ether hydrochloride (benadryl) and N,N-dimethyl-N′-benzyl-N′-(α-pyridyl) ethylenediamine monohydrochloride (pyribenzamine hydrochloride or triplennamine hydrochloride) is of value in these nasal allergic disorders. Using the latter drug, Feinberg[1] found that 64 per cent of patients with vasomotor rhinitis were helped. The usual dosage employed in treatment of vasomotor rhinitis with either benadryl or pyribenzamine is 150 to 200 mg. daily in three or four divided doses. The drug is preferably administered after meals and at bedtime.

The use of nicotinic acid is helpful in cases in which the "physical allergy" component is of greatest importance. It is of value because of its vasodilating properties and not because of its relationship to the vitamin B complex. It is good practice to administer nicotinic acid as follows: Injections are administered subcutaneously in daily doses beginning with 25 mg. These are increased by increments of 25 mg. daily to tolerance or until a dose of 100 mg. is attained. Subcutaneous injections of 100 mg. are continued daily for one month. If improvement takes place, an additional two months of parenteral therapy is advisable, after which nicotinic acid may be given by mouth instead of parenterally. When the drug is given by mouth, the dose tolerated is usually from 150 to 200 mg. daily in divided doses.

Histamine therapy[2] has on occasions proved useful in a few cases of vasomotor rhinitis.

Cauterization of the nasal mucous membrane in the region overlying the sphenopalatine ganglion with a 50 per cent aqueous solution of silver nitrate will at times give temporary relief. This had best be done by one well acquainted with intranasal procedures in the therapy of nose and throat diseases.

Iodides, administered orally in the form of the potassium or sodium salt, remain especially valuable in the care of patients whose primary complaints are referable to inspissated mucus in the nasopharynx and on the posterior pharyngeal wall. Such mucus is thinned, a procedure which relieves the nasal irritation associated with such dried secretions. In hypersensitive individuals, having an unwarranted fixation of their attention on their nasal functions, such treatment is especially helpful.

Comment

We have much to learn about nasal physiology and disturbances which may take place in the functions of the nose. This program for the management of vasomotor rhinitis has proved useful in many cases and has helped as a guide in the study of patients presenting the troublesome condition of vasomotor rhinitis.

CHOLINE AND OTHER LIPOTROPIC FACTORS

Mechanism of Action and Significance in Chronic Liver Disease

R. A. DOLAN, M.D.
Minneapolis, Minnesota

A LIPOTROPIC factor may be defined as an agent which prevents or removes an accumulation of excess fat in the liver. For the purpose of this discussion, the factors so far found to have a lipotropic action may be grouped on a biochemical basis. The first group consists of choline and the compounds which have been established as exerting their lipotropic action by virtue of their role in choline synthesis *in vivo*, namely, betaine and methionine. In a second group may be placed those factors whose exact nature and method of action are at present uncertain, namely, lipocaic and inositol.

Among those investigating these factors in the laboratory there has been and remains considerable difference of opinion as to the nature and mechanism of action of some of the lipotropic agents. While a certain unanimity of opinion regarding the choline group has been reached insofar as its use in the laboratory is concerned, the status of lipocaic and the pancreas factor is still a controversial point. This has partly been due to the many variables present:

1. The make-up of the dietary feeding used before and during the test period.
2. The duration of the test period.
3. The amounts of the test substances being used.
4. The experimental animal.

It is the purpose of this discussion to make an attempt at resolving some of the divergent opinions now extant, by a presentation and comparison of the experimental findings to date.

It is also important to note the considerable significance of these experimental findings in the pathogenesis of the cirrhotic states. Cirrhosis is considered by many to be the end point of a process initiated by fatty infiltration. On this basis the lipotropic factors have been used as therapeutic agents in the acute, infectious and toxic forms of hepatitis and in established cirrhosis with varying results.

The Choline Group

Choline is an amine—trimethyl beta hydroxy ethyl ammonium hydroxide—$(CH_3)_3$ N.OH. CH_2CH_2OH. In a consideration of its lipotropic action, the process of fat transport from the liver must be understood. As neutral fats and fatty acids are insoluble in blood, they must be converted to phospholipids. Paul and his associates stated in 1947 that fat metabolism is not a simple breaking down of the ingested fat for immediate use and a storing of the remainder in inert depots. Storage is a phase in a dynamic equilibrium. The essential factor is fat transport. It is thought that this change to phospholipids in the liver is effected by the incorporation of phosphoric acid and choline into the fat molecule. In 1944 Peters, Kendrick and their associates stated that choline furnishes labile methyl groups for the synthesis of phospholipids from fatty acids. However, in 1946, McArthur, investigating the incorporation of a choline homologue into liver phospholipids, found arseno-choline, which possesses no labile methyl groups, to be lipotropic and incorporated in the phospholipid molecule after experimental feeding.

The bulk of the evidence to date indicates that choline is the most powerful of the lipotropic factors in experimental work on the rat and is effective in reducing the total lipid level in the liver in all fractions.

The speed and strength of action of choline depends on several factors:

1. The constituents of the diet presented to the rat before and during the test period.
2. Choline is concerned with lipid phosphorylation in the small intestine as well as in the liver, and hence, part of the ingested choline will be utilized in the intestine. Artom and Cornatzer in 1946 reported their experiences in this connection with radioactive phosphorus.
3. While choline is known to act by increasing the rate of phospholipid "turnover" in the liver, the rate of loss of lipids from the liver, i.e., lipotropic activity, does not necessarily parallel this rate of turnover. Horning and Eckstein in 1946 reported their investigations on this subject using radioactive phosphorus. It was concluded that an increase in phospholipid activity does not necessarily connote an increase in fat metabolism. Only

when the phospholipid shift is from liver to blood is lipotropic activity manifest.

There is little doubt that plasma phospholipids are formed in the liver, and hence, the phenomenon of lipotropism occurs. Entenman and his collaborators in 1946 found in *normal* dogs that specific activity of the choline-containing phospholipid phosphorus of the liver, as measured with P 32, is higher than in plasma phospholipids. This would suggest that nearly all the phospholipids of the plasma are formed in the liver.

4. Choline has other actions in addition to its lipotropic effect. It is, of course, a precursor of the neurohumor acetylcholine. Its deficiency has been found to produce hemorrhagic kidneys in experimental animals, an occurrence apparently closely related to the development of fatty livers. Best and others have emphasized its role in growth. Several observers have noted that the strength of the lipotropic action can be impaired under certain circumstances because a portion of the ingested choline is taken up with the above processes.

Betaine and Methionine

It is now accepted almost unanimously that the alkaloid betaine and the amino-acid methionine are not unique as lipotropic factors but exert an effect by supplying methyl groups for the synthesis of choline *in vivo*. The availability of methyl groups in methionine is indicated by its formula:

$$CH_3.\ S.\ CH_2.\ CH_2\ (COOH).\ CH\text{-}NH_2.$$

In 1946, Du Vigneaud and his group investigated betaine in transmethylation reactions. They labelled the methyl groups with deuterium and the glycine component with N 15. They also fed glycine labelled with deuterium. These two compounds were fed to pairs of rats receiving choline-free diets. In the betaine animals, choline and creatine were isolated from tissues and analyzed for deuterium and N 15. The glycine animals were similarly investigated for deuterium. Du Vigneaud's results show that methyl groups from betaine appear as quickly in tissue choline as when choline is given. This would signify a direct conversion. However, the N 15 of the glycine moiety apparently does not undergo this direct conversion. It appeared rapidly in tissue glycine and much more slowly in tissue choline. It is probable that the N 15 goes to the choline through glycine and ethanolamine. The dimethyl glycine was found to contribute a very small amount of methyl groups to tissue choline, but did not appear to exert a lipotropic effect.

Du Vigneaud presented similar evidence to the above to show methionine's action in lipotropism.

The ability of methionine to offer labile methyl groups has also been found valuable in the later stages of the process leading to cirrhosis. Best and Taylor state that methionine prevents necrosis and cirrhosis. It supplies methyl groups for the formation of cystine which prevents necrosis, and itself supplies sulfur which is anti-necrotic, and by transmethylation forms choline which prevents cirrhosis. It is also largely responsible for the lipotropic effect of a high protein diet.

Inositol

The vitamin inositol, a member of the B group, whose formula is $CHOH\ (CHOH.CHOH)_2\ CHOH$, and which resembles a hexose, has definite lipotropic action but its mechansim is uncertain. As can be seen from the formula, it probably does not act as a transmethylator and is not known to be involved in the synthesis of any other factor, though it is known to act with choline in a synergistic manner. Handler in 1946 stated his belief that inositol either forms inositol phospholipids or acts as a phosphorylating catalyst. As will be indicated later, some workers think it may be an active factor in lipocaic.

Lipocaic

The considerable divergence of views which prevails in the field of lipotropics is greatest in the consideration of the anti-fatty liver factor of the pancreas. This controversy began when Dragstedt postulated a second internal secretion of the pancreas in addition to insulin which he called "lipocaic," a word derived from the Greek meaning literally "I burn fat." Dragstedt, Prohaska and Harms reported their findings in 1936. In one phase of their report they were concerned with the relation of pancreatic juice to fatty infiltration and degeneration of the liver in the depancreatized dog. In their first group of tests they effected a total loss of pancreatic juice through a pancreatic fistula. The dogs were fed a meat, bread and whole milk diet. Of four dogs, two developed subcutaneous abscesses and died in thirty days. Moderate fatty liver infiltration was noted at post mortem. Another died at

twenty-three days and had slight infiltration. The other dogs were sacrificed at twenty-six, thirty-five, thirty-nine and forty-three days postoperatively, and no excess liver fat was seen.

In their second set of experiments the pancreatic ducts were ligated and divided. (It was found that duct ligation caused acinous degeneration, so that there was no opportunity for pancreatic juice to be formed and absorbed directly into the blood stream.) The pancreas was separated from the duodenum. The animals died in less than eighty-three days from degeneration of the pancreas, but only two animals showed liver infiltration.

Further work with the depancreatized dog showed that 25 grams of raw pancreas per day was required to keep the liver normal. The amount of choline required to prevent hepatic infiltration was found to be 1.0 grams. This was calculated to be fifteen times as much as was present in 25 grams of raw pancreas. Beef brain, containing large amounts of lecethin and choline gave no protection against infiltration in one dog. In another dog beef liver was found to be ineffective. Dragstedt concluded from these findings that the absence of pancreatic juice is not the cause of the rise in liver lipids. He also asserted that the liver change noted in some animals after duct ligation was minimal. Sections of the liver tissue were reproduced to show the very extensive zonal infiltration occuring in some cases and the very slight collections of fat droplets in others. It was considered that the beneficial effect of raw pancreas is not due to contained enzymes or to improvement of digestion occasioned by those enzymes. Choline was not thought to be the factor responsible.

These investigations are perhaps open to certain critical analysis for the following reasons:

1. No mention was made of the considerable amounts of choline and methionine undoubtedly present in free or combined form in the meat diet used.

2. The duration of the test periods was not nearly sufficient in the light of later work.

3. The fact that many of the dogs died could not but have a vitiating effect on the value of the findings.

In their second 1936 report the results of observations on a pancreatic substance which permitted survival and prevented liver changes in the pancreatectomized dog were given. Forty-five dogs received complete pancreatic excision. Eight dogs received no dietary supplement and died in two or three weeks. (All dogs in these experiments were fully maintained on insulin.) The livers were markedly fatty. Fractionations of the pancreas were undertaken in an attempt to secure the liver-protecting substance. Several different extracts from approximately 100 grams of pancreas were fed postoperatively to the dogs whose livers indicated fatty infiltration on biopsy. Three to four weeks later another biopsy was taken and the two specimens compared. The extracts used were as follows:

1. A fat-free alcohol extract.
2. An ether extract.
3. The pancreatic residue.
4. A salt solution extract of the pancreas residue.

The ether extract contained mainly the pancreatic lipids and had no protective effect. The fat-free alcoholic extract given in doses of 1.0 to 1.5 grams of dried substance was lipotropically active. The pancreatic residue and its saline extract were also effective. The substance, then, was considered insoluble in ether and soluble in alcohol and 5 per cent saline. It was not considered present in pancreatic juice. The general conclusion was, therefore, the discovery of a new pancreatic hormone which under normal conditions plays a role in fat transport.

In 1946 Dragstedt and his associates studied the effect of oral and parenteral lipocaic and oral inositol on the dietary fatty liver of the white rat. In this report it was admitted that the status of lipocaic as a true hormone is a matter of debate. It was felt, however, that lipocaic is a distinct substance apart from choline and its precursors.

In answer to the conclusions of McHenry and Gavin that the preparations of lipocaic they used contained enough inositol to account for lipotropic activity, Dragstedt stated that inositol was entirely ineffective in preventing or curing fatty livers in depancreatized dogs even in doses as large as the active preparations of lipocaic. As these pancreatic extracts could not be pure inositol, lipocaic activity could not be accounted for by the presence of inositol.

Other Investigations on the Antifatty Liver Pancreas Factor

Entenman and Chaikoff and their associates presented reports beginning in 1941 on their work with the totally pancreatectomized dog. In 1941 they investigated the possibilities of choline as the factor in the pancreas producing lipotropic phenomena.

Their researches, in contrast to those in Dragstedt's laboratory, showed that duct ligation of the pancreas produces fatty livers in the dog and that with ligated ducts fresh pancreatic juice inhibits high liver lipid levels. They felt that this means that in the normal animal, pancreatic juice is responsible for the maintenance of a normal liver. As choline performs this function as well as pancreatic juice, perhaps it is the responsible pancreas constituent. They felt, however, that the question is still in doubt as to the real relation, if any, between choline effect and pancreas effect. They pointed out, as others have, that lipogenesis and lipotropism in the rat and dog liver are not necessarily identical processes.

Their experiment on choline and pancreatic extract was carried out on twenty-five dogs. Each dog received a lean meat and sucrose diet supplemented with vitamins for one to three weeks preoperatively. Postoperatively the sucrose diet level was raised and insulin was injected daily. The dogs were given raw pancreas in addition to the basal diet to keep the liver free from fat until they had recovered completely from the effects of surgery. When the dogs were adjudged fit insofar as appetite and the state of the operative wound were concerned, selective feedings with two pancreas fractions, "AR" and "KAR," and choline were begun. Livers were removed for analysis at intervals. Fraction AR was the pancreas residue after extracting with acetone and ether. It was stored at 18° C. until used. One gram was equivalent to 5.5 grams raw pancreas and was found effective lipotropically for as long as twenty weeks. The KAR fraction was a thoroughly autoclaved (20 pounds pressure for thirty minutes) amount of fraction AR. It was found lipotropically inactive in doses of 4 grams per day, indicating that the lipotropic substance is heat labile.

The *minimum effective dose of choline* (the amount required to keep the liver fat normal—approximately 2.6 per cent—4 per cent total fatty acids by weight—for fifteen to twenty-two weeks) was found to be 36 mg./Kg. A dosage of 15 mg./Kg. was not effective. As 250 gm. of raw pancreas contains 575 mg. of choline, choline was more than sufficient to account for the effectiveness of this amount of pancreas.

It was found that 250 grams of autoclaved pancreas gave full protection and also was curative. Therefore, choline may be a heat-stable factor. But 1 gram of AR gave full protection, and at most it contained 13 mg. of choline, an amount well below the minimum effective dose.

The destruction of the active principle in AR by heat suggests that the choline in AR was not involved in the lipotropic action.

But while these experiments showed that AR effect was not due to choline, it has not been ruled out that additional amounts of choline are made available to the organism by the presence of AR in the intestinal tract.

In 1944, further work on the pancreas factor was reported from the laboratory of Entenman and Chaikoff. As before, dogs were carefully chosen as to appetite; they were fed high protein diets with caloric and vitamin supplements preoperatively and raw pancreas for a varying number of weeks postoperatively. The regimen was kept up during the test period, the only variable being the test substance substituted for the raw pancreas. The test period was sixteen to twenty weeks. It was shown that a normal liver could be maintained on any one of the following constituents (not necessarily minimum doses):

1. 5 gm. raw pancreas.
2. 300 mg. choline chloride.
3. 500 c.c. pancreatic juice.

It was noted that the consistent development of fatty livers takes as long as twenty weeks. It was further shown that pancreas in the intact animal or pancreas feedings in the excised animal does not exert a storage effect.

Pancreatic juice fed to five dogs in the test period gave fatty acid levels of 3 to 7 per cent. It was concluded that the pancreas produces an external factor present in the juice. Lipocaic was tested during the experimental period and blood

samples were checked for lipids and cholesterol at intervals. Their *results* showed:

1. The fraction AR (described above) gave *liver lipid* values of less than 4 per cent. Six dogs received lipocaic for ten to fourteen weeks; none had normal liver lipids, and three showed over 40 per cent. This lipocaic was derived from 15 grams of raw pancreas.
2. Lipocaic in amounts equivalent to 100 grams pancreas was administered for as long as twenty weeks. Only two dogs had a near normal fraction. Total liver fatty acids ran as high as 40 per cent.

Blood lipids.—Previous work had shown a fall in blood lipids when pancreas feedings were withheld in the excised dog. The lipids were normal with pancreas feedings. In the present experiment, blood lipids were checked before excision, during pancreas feeding and then up to twenty weeks during lipocaic feeding.

Results.—All dogs on raw pancreas maintained normal levels in blood lipids. There was a fall in *all* fractions, including cholesterol, during the test period on lipocaic. 5.5 gm. of pancreas were found sufficient to keep postoperative levels higher than preoperative levels.

Their conclusion.—Lipocaic is a poor source antifatty liver factor of the pancrease.

The mechanism of action of the pancreas antifatty liver factor.—Fatty livers develop even when diet is rich in choline or labile methyl groups, but is prevented by free choline or pancreas fractions. It has been shown that choline-free fractions of pancreas are effective lipotropically. With increased liver fat and when pancreatic juice is withheld, blood phospholipid values drop. It has been found that 95 per cent of plasma phospholipids are of the choline-containing type. This is strong evidence that *circulating* choline is deficient in the dog lacking intestinal pancreatic juice. After ligation or excision, plasma choline dropped from 61.3 to 46.6 mg./100 c.c. and remained below normal for as long as one year. One gram of fraction AR prevented such a fall, or raised the level to normal after it had fallen. It appeared from this work that the pancreas contains a substance highly active in choline metabolism.

Discussion.—Phospholipids apparently serve as choline transports as well as fat transports. As these phospholipids are practically all choline-containing, it might be concluded that they are connected with the physiological activity of circulating choline. The action of pancreas fractions in increasing the plasma choline is not dependent on choline as such in diet. The extra choline must come from tissues or synthesis.

When fatty livers occur, there must be an interference with the mchanism by which bound dietary choline and methionine are made available or in the synthesis of choline from methyl donors. Methionine was found lipotropically effective in depancreatized dogs in feedings up to twenty weeks. As methionine was shown previously to be a precursor of choline by virtue of its labile methyl groups in rats and dogs, no pancreas supplement was needed. Entenman and his associates concluded that the pancreas factor is not concerned with *in vivo* synethesis of choline or its lipotropic action. They thought that the pancreas factor might be responsible for freeing the bound methionine in protein in the diet. They therefore postulated the pancreas factor as a *proteolytic enzyme.*

General Conclusions in Regard to the Pancreas Lipotropic Factor as Compared to Choline

1. Most investigators are agreed that there is a specific substance manufactured in the pancreas which is not choline or one of its precursors, and which has a lipotropic action, direct or otherwise.
2. Lipocaic, as described by Dragstedt and as manufactured by commercial houses, does not give the same results in the hands of different investigators. It might be legitimately concluded that the name *lipocaic* does not at present represent a thoroughly standardized pancreatic extract in terms of potency and lipotropic effect. It can also be stated that there is, as yet, no conclusive proof that lipocaic represents a true hormone. While the experiments of Dragstedt seemed to show that pancreatic juice was not active lipotropically, other investigators found pancreatic juice very effective in preventing fatty livers in dogs. The evidence to date would indicate that the term *lipocaic,* as connoting an internal secretion in the pancreas which is active lipotropically, is not valid. However, there seems no doubt that the pancreas does contain a factor active in clearing fat from the liver which is neither

a member of the choline group nor inositol. Whether it acts directly on the liver fat, as does choline, remains a question. Present evidence points to an indirect action. It may act by releasing choline, or one of its precursors, from a bound form to a form freely available for direct lipotropic activity. At the present date it appears that choline is the only factor that lowers liver lipids by direct combination with the liver-fatty acids to form phospholipids.

Experimental and Therapeutic Findings in Regard to Choline and Chronic Pathological Processes in the Liver in the Laboratory Animal and in Man

As choline and methionine have been used in several clinics for the treatment of acute and chronic affections of the liver in man, it is of value to ascertain the relationship of the lipotropic factors to the pathological process. Copeland and Salmon in 1946 presented evidence that choline deficiency in the rat may produce the steps leading to cirrhosis and even neoplastic change.

Eighty-eight rats were given a low choline diet consisting of peanut meal, casein, sucrose, lard and salt, with added vitamin supplement (which included inositol). Nineteen animals received choline throughout the test period, and served as controls. It was found that a complete lack of free choline resulted in the death of the rats before advanced liver change could be noted, so the test animals were given minimal amounts of choline at intervals merely to keep them alive. Twenty per cent died in six weeks. The remainder were kept alive for several months, though they showed gradual general degeneration.

At the end of twenty-eight days, biopsies showed swollen heavy livers; fatty acids and neutral fats were demonstrated in globules. At three months there was fatty infiltration zonally and degeneration—a "pre-cirrhotic state." This was judged by the increase in fibrous tissue and a rapid rate of cell destruction and regeneration. At eight months a "hobnailed" liver was produced—a typical cirrhotic picture. There was perilobular fibrosis, and intralobular strands of connective tissue were seen. Numerous mitotic figures and giant cells were observed. Cells were occasionally arranged in sheets, whorls and acini-like formations. In 30 per cent of the rats surviving eight months there were areas resembling adenocarcinoma—cords of cells, solid masses and acini-like whorls. This growth was made up of stratified epithelium. The controls did not show any neoplastic tendency. These authors concluded that a definite sequence of events, from fatty infiltration through established cirrhosis, occurred in the rat in choline deficiency.

On the subject of *lipotropic agents and chemical poisons* in the liver, most workers are now agreed that choline does not prevent fatty infiltration in $CHCL_3$, CCL_4, phosphorus and other poisoning, but does hasten recovery by removing fat.

Therapeutic trials of the lipotropic agents in *infectious hepatitis and chronic liver disease,* including the enlarged fatty liver with early fibrosis and the shrunken liver of atropic cirrhosis, have so far been equivocal.

Paul, Daum and Kemp in 1947 used choline in several cases in which they felt there was a disorder in fat metabolism. They felt that malnutrition is a major factor in cirrhosis. In a normal diet, sufficient lipotropic factors are supplied to convert ingested fat to phospholipid. Due to dietary imbalance (high fat, low protein, low carbohydrate and low vitamin) in *alcoholism,* a fatty liver is initiated, and irreversible changes may follow. By reversing these factors and adding choline, they felt that fat would be mobilized and appetite would improve. In *diabetes mellitus* they considered that normal utilization of endogenous insulin is dependent on normal liver function. When this function fails, extra insulin, even exogenous, is required. Liver dysfunction and damage is known to occur in a high percentage of diabetics, particularly in acidosis and coma. Hyperglycemia and glycosuria can result from obesity alone. They have found benefit from choline in diabetic liver damages, psoriasis, burns and the hepato-renal syndrome.

In their therapeutic trials, Paul and his group used choline dihydrogen citrate, 25 per cent in a syrup vehicle, which they found the most palatable of the choline salts. The standard amount of choline used was 3 grams per day, given in divided doses three times per day. Their nondiabetics received a low-fat, high-protein diet while the diabetics received a routine diabetic diet. The trials were first run on normals. The average normal values without choline for the blood lipid fractions were as follows:

Total fats	500-700 mg. per cent
Phospholipids	195-255 mg. per cent
Cholesterol	150-200 mg. per cent
Cholesterol esters	60- 70 mg. per cent

In these controls there was wide variation from one individual to the other, but each individual tended to maintain a fairly constant lipid fraction *ratio* when choline was given to these controls for twenty days. Each fraction tended to be stabilized nearer the average normal. Phospholipids showed the least change but tended to go higher when *seventeen cirrhotic* persons were checked for fifteen days on choline. There was no uniform change, but there appeared to be a tendency for one or more of the values to approach normality. There seemed an over-all improvement in the blood lipid picture which previously had shown low values. In *diabetes mellitus* two groups of five each were treated, one with choline, the other without. The choline-treated patients showed a definite trend toward normal values. For a larger series of twenty patients in the control group and twenty in the "choline group," twelve controls had a normal total fat reading while eight had an abnormal reading. In the choline-treated group, seventeen showed normal readings while three had abnormal total blood lipids.

Clinically, there was an undeniable improvement in general well-being, particularly where abnormal fat metabolism was recognized before treatment. There was thus a correlation between the laboratory findings and the clinical response as measured by appetite, feeling of well-being and vigor. When choline was withdrawn, patients reported feeling less well in three weeks.

General Conclusions Regarding Lipotropics and Liver Pathology

1. From the experimental evidence reviewed, it seems reasonable to conclude that cirrhosis or irreversible fibrosis of the liver is an end result of a process initiated by fatty infiltration. One laboratory has shown that neoplastic change may occur with or following fibrotic change, and implicates choline deficiency as a possible carcinogenic factor. This postulation requires considerably more investigation, however, before any definite relationship can be established.

2. This fatty infiltration seems due to a negative rather than a positive factor. The bulk of the above evidence indicates that this negative factor is a lack in the diet, or in the organism, of substances which directly or indirectly have a lipotropic influence; and in most instances, addition to the ingested diet of these substances effects a reversal of the infiltrative process in the liver, with a consequent rise of the lipid fractions in the blood.

3. The most consistently reliable of these factors has been shown to be choline, which exerts a lipotropic effect in rat, dog and man. The pancreatic factor is also effective, though to probably a lesser degree. As pointed out above, however, it may act only indirectly by effecting in some way an improvement in choline metabolism. At present, choline seems the only compound which acts by direct molecular combination with the liver fatty acids and neutral fats.

4. Considerably more experimental and therapeutic trials are required before choline and similar agents can be adopted as definitive therapy. While it seems true experimentally that choline exerts a beneficial effect by clearing the fat from the liver, therapeutic trials have not always yielded unequivocal results. The possibility of toxic effects must be taken into consideration. Particularly, the possibility of circulating acetylcholine appears of definite importance.

5. Future experimental work should be directed toward the use of the lipotropic factors as prophylactic agents rather than curative drugs. The prevention and removal of excess liver lipids in the early and acute stage of liver disease should theoretically be possible with choline. But there is no evidence that the lipotropic agents should have any beneficial effect on the established fibrotic state, except where fatty infiltration is still a part of the pathological picture.

Summary

1. The term *lipotropic* was defined, and the substances which appear to produce a lipotropic effect were briefly described as to their experimental effects and relation to chronic liver disease.

2. The members of the choline group, choline betaine and methionine, were compared and experimental evidence regarding their effects was reviewed.

3. The evidence relating to inositol was presented.

4. The laboratory results on lipocaic and the antifatty-liver factor in the pancreas were reviewed and compared. The nature of the pancreas lipotropic factor was discussed.

5. The findings in experimental and therapeu-

tic tests of the lipotropic agents in relation to liver pathology were presented. The significance and limitations of choline and related compounds in liver disease were pointed out.

THE TREATMENT OF OPEN WOUNDS OF THE HAND

(Continued from Page 1192)

for suturing of the digital nerves. There seems to be the impression that these nerves will regenerate spontaneously and that repair is not necessary. There is also the impression that the nerves are too small to suture. Both of these impressions are wrong. While it is true that overlap will compensate to varying degrees for loss of innervation on one side of a finger if the other side is intact, this overlap is never as good as the normal and may be a real handicap. If both digital nerves have been divided, the sensation has no chance of returning to the finger. In answer to the statement that the digital nerves are too small to suture is the experience of many surgeons in suturing them. They are not nearly as small as one thinks, and three or four fine sutures can easily be distributed about their circumference.

Fractures and dislocations should be reduced at the primary operation if the wound is such as to permit closure. Reduction should also be done even in older wounds unless there is a severe spreading infection already present which precludes any manipulation. Joint capsules should be sutured in any wound in which operative intervention of any sort may be undertaken, even if the wound cannot be closed afterwards. Internal fixation of bones may be undertaken if the wound is seen early. Ordinarily, most fractures of the hand can be reduced and held in reduction by molding the hand into the position of function or into the grasping position. In very few instances it is necessary to apply traction to the fingers to maintain reduction. In Bennet's fracture it is often advantageous to apply traction because of the shearing nature of the injury and the difficulty of holding the first metacarpal in position against the pull of the powerful flexors and extensors of the thumb. We have, however, in a number of instances been able to reduce and maintain reduction of the base of the first metacarpal on the universal hand splint which simply holds the hand in the position of function.

(To be concluded in December issue.)

UNRECOGNIZED FRACTURES IN HIGH SCHOOL ATHLETES

W. K. FOSTER, M.D., and JOHN C. WELLS, M.A.
Minneapolis, Minnesota

AT the close of our 1945 football season the coach of our championship team had three of his players report with minor injuries of considerable duration. He referred them to our medical department where x-rays were taken which showed that each of them had a fracture that had been incurred earlier in the season. This surprised us considerably because this particular coach, in addition to being very well trained, had always been unusually prompt and efficient in taking care of his injuries. Apparently all these injuries had been considered so insignificant that the boys had not reported them to the coach or had deliberately concealed them. These three cases led us to make a study of our unrecognized fractures. By this we mean those fractures where the athlete continued to compete, without medical advice and in spite of his injury, until we later determined that he had a fracture. All of these cases followed about the same pattern. The boy had not thought his injury to be of any importance and had not notified his parents or reported to the family doctor for medical care. Instead, he had continued to compete until the coach sent him in to have the extent of his injury determined before using him further in competition.

Our study has been complicated by many factors. The parents often oppose the boy's playing football, and he consequently conceals his injury or explains it, if he has to, as a strain. Coaches are often so absorbed in coaching that they dispose of their injuries by telling the boy to "go see the doc" and then forget all about it. Coaches often bear down on the boys so hard that they will undergo all sorts of torture with injuries rather than be called a sissy, or yellow, or otherwise have their courage ill spoken of. Boys are often afraid that their teammates and friends will think they haven't any "guts," and so they take a Spartan attitude toward their injuries. As a result it is almost impossible to get boys to use a crutch or a sling or carry other visible signs of injury, except when the injury is a major one and some sort of protection allows no choice in the matter. If some of his teammates are present, the boy will usually submit without complaint to the manipulation of an injured part and will allow a fracture to be reduced without anesthesia.

After seeing the three cases mentioned above, we searched our records and found many similar ones. With some reluctance and intrepidation we began to x-ray all our strains. We soon found that one out of every four or five strains was, in reality, a fracture. We now have become so suspicious of strains that we have to be shown that one is a strain by proving by x-ray that it is not a fracture.

It might be well at this point to make it clear that we are interested in these cases primarily from an athletic point of view. We are not trying to provide medical or surgical care. If there is a chance that athletics under any condition will do harm to a boy, we wish to cut that chance to a minimum if not to zero. There are, of course, certain hazards inherent in athletics, but beyond them we wish every extra hazard eliminated. We must know at the earliest possible moment if a boy is unable to play. We prefer not to use any haphazard method in finding this out. It is our mission and duty to train youth properly. We wish to do this with the least chance of harm to the youth. With this in mind, it then becomes our duty to disqualify our unfit at the earliest possible moment. It is not enough to bar the weaklings and handicapped by a preseason athletic examination. Each boy who suffers an injury should be appraised physically as soon as possible to determine if further competition is permissible. Much harm may be done by leaving the matter to the family or even to the family doctor. Often the family is reluctant to incur medical bills and tends to muddle along if the injury is not extremely severe.* If the boy is seen by a doctor, parents often complicate things by demanding that the

Dr. Foster is Medical Director and John C. Wells is Assistant Director in charge of interschool athletics in the Minneapolis Public Schools.

*This muddling along may involve paying no attention whatever to the injury. It may take the turn of ill-timed advice, such as going ahead and "work it out." It may result in the boy's getting into the hands of an amateur self-appointed "bone setter." It often results in a lot of heat being put on the coach, by well-meaning friends and relatives, to use the boy in spite of his injury. These are only a few of the things that can happen.

Fig. 1. X-ray in Case 1 showing a transverse fracture at the distal end of the fifth right metacarpal.

Fig. 3. X-ray in Case 3 showing an oblique fracture of the fifth metacarpal bone.

school pay the bill. Our city attorney has held that we cannot legally do this. The doctor then cannot be expected to co-operate wholeheartedly in a deal where he stands a major chance of being euchered out of his fee—certainly not when you consider that every fracture is a possible lawsuit. Often the family doctor does not have an x-ray, and even if he does he is likely to appraise the injury from a medical or surgical standpoint rather than from an athletic standpoint. The injury may be of minor importance medically or surgically and yet be of major magnitude from a competitive view. Many doctors prefer not to treat these cases because in one way or another they crowd the remainder of their practice all out of proportion to their medical or surgical importance. It is often hard enough for us to handle these cases when we hold all the factors in our own hands. To allow any slack to slip into the situation is to be unfair to both the student and to his coach. The boy should be allowed to play if he is able, and forbidden to play if he is not able. The coach should be given this information at the earliest possible moment. In carrying out our policy, we have no desire to invade the field of medicine beyond the bounds of urgent athletic necessity. If a boy has a serious injury, such as a broken arm or leg, our coaches bar him on the spot. We have a doctor in attendance at each game to advise the coach and give first aid. If the injury is of a less evident nature, and the matter has not been attended to by the family or the family doctor so that the coach knows where he stands, then he appeals to our medical department for a verdict. This procedure led us to x-ray many insignificant injuries in order to give an exact and just answer. In doing this we have come to the conclusion that every moderately severe strain of a foot, ankle, lower leg, finger, hand, wrist or forearm may be, and often is, a fracture.

We present the following case histories.

Case Reports

Case 1.—R. A. of P. H. High School was sent to us on November 5 at the close of the football season and at the opening of the basketball season. His coach requested that we look at his right hand. He stated that he had hurt it early in September and had had trouble with it all season, not enough however to have it looked at by a doctor. An x-ray revealed a transverse fracture of the distal end of the fifth right metacarpal bone.

Case 2.—N. S. of P. H. High School was sent in by the same coach along with Case 1 to have his right hand looked at. He gave a history of having hurt his right hand in September, or early in the football season, at about the same time his teammate above was injured. Like his teammate he had played football all season and had not sought medical advice or care previous to this time. An x-ray revealed an oblique fracture of the fourth metacarpal bone extending the full length of the bone.

Case 3.—B. H. of P. H. High School, was sent in with Case 1 and Case 2 with a history practically identical with theirs. He had hurt his left hand early in the season. An x-ray of the left little finger showed an oblique fracture of the proximal phalanx extending through nearly the entire length of the bone. He, like the other two boys, had continued to play out the season when he could get into the game.

Fig. 4. X-ray in Case 4 showing an oblique fracture of the proximal phalanx of the left middle toe.

Fig. 5. X-ray in Case 5 showing an oblique fracture of the proximal phalanx of the left little toe.

Case 4.—A. P. of R. High School was sent in by his coach with a history of having hurt his left foot two weeks earlier while doing a giant roll on the parallel bars. He had sought no medical advice previous to the time we saw him. An x-ray showed an oblique fracture of the proximal phalanx of the left middle toe.

Case 5.—A. H. of E. High School was sent in by his coach two weeks after injury. He had received no medical care before coming in. An x-ray showed an oblique fracture of the proximal phalanx of the left little toe.

Case 6.—A student in R. High School was sent in two weeks after injury. He had sought no medical advice. An x-ray showed a greenstick fracture of the fourth right metastarsal bone.

Case 7.—G. C. of W. High School was sent in by his coach for an injury sustained four days earlier while boxing. He had had no medical care before coming in. An x-ray showed an impacted fracture of the proximal end of the left first metacarpal bone.

Case 8.—A student of S. High School was sent in a week after injury complaining of a strained thumb. An x-ray showed a transverse impacted fracture of the right thumb.

Case 9.—R. K. of S. High School was sent in by his coach to see why he could not hold a football while playing at the quarterback position. He gave a history of having hurt his left hand in a game on October 9. He came to us on October 19, having had no previous medical care. An x-ray revealed an oblique fracture of both the fourth and fifth left metacarpal bones.

Case 10.—S. C. of P. H. High School was sent in by his coach on October 21 with a history of injury to his right hand five days earlier in a regularly scheduled football game. An x-ray showed an impacted fracture of the proximal end of the first phalanx of the right hand. He had had no previous medical care.

Case 11.—J. K. of N. High School was sent in by his coach for a strained ankle. An x-ray revealed a previous fracture of the medial malleolus of the left tibia of two years' standing, with very poor or no union at all. He had not revealed this condition to us and had played until an injury occurred which the coach was now checking up on.

Case 12.—Z. S. of N. High School was sent in by his coach for a Charley horse sustained three days earlier. He gave a history of having been kneed in a football game. He had had no previous medical care. An x-ray showed an oblique fracture of the left fibula, at the junction of the upper and middle thirds.

Case 13.—W. J. of P. H. High School was sent in by his coach complaining of a pulled muscle in his left lower leg. He came in on September 18 and dated his injury as of September 6, twelve days earlier. An x-ray revealed a transverse fracture of the left fibula at the junction of the upper and middle thirds. This boy had been raring to get into the game every time the coach would use him.

Fig. 6. X-ray in Case 9 showing oblique fractures of the fourth and fifth left metacarpal bones.

Fig. 7. X-ray in Case 11 showing a fracture of the medical malleolus of the left tibia of two years' standing.

Fig. 8. X-ray in Case 13 showing a transverse fracture of the left fibula.

Case 14.—K. R., a supervisor of Minneapolis Public Play Grounds. We present this case not because it is a high school athletic injury, or because we wish to escape the unlucky number 13. We present it because it shows what an athletic coach may run into in handling these cases. It shows that the wisest of us slip up now and then. We did not dig this case out of our files. He came in while we were working up this article, and we decided to present his case with the others.

This man has been engaged in athletics and athletic activity as a life work. He graduated from the Springfield Training School of Springfield, Massachusetts, and immediately entered playground work where he spent forty years. He has spent his whole life in contact with boys at the High School level.

During the first snowstorm of the winter his car got stuck, and a small tractor was called out to pull him back on the road. He stated that he got too close to the tractor and it nudged his left lower leg and foot. He was not clear just how it happened, but he sustained a strained left ankle. Over a month later his ankle continued to swell. He came in to see why he was so slow in recovering. An x-ray showed a fracture of both the tibia and the fibula at the ankle joint, each distal fragment being from ½ to 1 centimeter in size. He had had no medical advice or care before coming to us.

We have seen many more of these cases, but presenting them would only be a repetition of those here shown. We have not included any cases where a fracture was expected before an X-ray was taken. We have tried in all cases to make a diagnosis before x-ray was used, but found no way of being even nearly certain. Many cases where symptoms almost certainly indicated that a fracture was present were found on x-ray to be only severe strains. On the other hand, the symptoms in many cases were so mild that a fracture was considered almost certainly not present, but was found on x-ray. We were not able to differentiate between a strain and a fracture except by x-ray. Histories in these cases were usually useless, especially in football where the pitch of excitement is so high that the boy is not able to tell how and when he got hurt.

Conclusions

1. Every strain is a possible fracture.
2. A definite diagnosis can be made only by x-ray.
3. Many fractures sustained in athletics are never diagnosed.
4. Football is the outstanding producer of fractures in high school sports.
5. Most unrecognized fractures in high school athletes occur in the hands, wrists, forearms, feet, ankles, and lower legs.
6. It is the duty of the athletic department in high schools to make an all-out effort to keep boys with recent fractures out of competition until the fracture is well healed.

Discussion

JOHN C. WELLS, assistant director in charge of interschool athletics, Minneapolis Public Schools, Minneap-

olis: The Minneapolis public school athletic program involves competition in twelve sports by several thousand boys. We try in every way possible to give thorough medical examination, competent coaching, standard equipment, adequate supervision, good officiating and proper care of injuries as they occur. In spite of many precautions, our experience shows that many so-called unimportant bumps and bruises have turned out to be fractures, and we have labeled these "unrecognized fractures."

Our athletic injury problem must of necessity be a large one in Minneapolis. We have eleven senior high schools which compete more or less in a round robin in twelve different sports. We have examined 2,382 boys for athletic competition in the fall quarter of the present year. Our top school had 512 boys certified for athletics in the last three months of 1947. About half of these boys sustain some bumps, bruises or strains of varying degrees of severity. Most of the serious injuries are taken care of by the family doctor. Many are seen by the team or game physician. Some are sent by the coach to our medical officer. Many are taken care of by the coach or team trainer. It is probable, we are sorry to say, that some are not attended to by anyone.

We believe that no athlete should be permitted to participate in athletics unless he is registered in the Minnesota State High School League Accident Benefit Plan. This insures a medical examination and some coverage for medical expenses in case of injury. Many times injuries are belittled because of possible expenses involved in medical examination and treatment. If boys are registered under the plan, there is little excuse for neglecting these injuries, as a liberal allowance is provided for sprains and x-ray.

Dr. W. K. Foster, our athletic medical adviser, has made a report of these injuries, and it is our hope that others who deal with athletic injuries may profit from our experience.

Frank Cleve, coach at Patrick Henry High School, Minneapolis: Most coaches of high school teams have a general idea of injuries. Those that have majors in physical education also have studied the anatomy and physiology of the human body.

I believe that the majority of coaches will not play nor contact-scrimmage a boy who is injured to the extent where it may be more injurious to this boy. However, many injuries are not serious enough to keep a boy from playing. Many boys are slightly injured and do not report this to the coach or manager. Also, many minor ailments are not thought serious enough to keep a boy out of practice. I am thinking of normal bumps and bruises, also slight strains and sprains.

The equipment and care of injuries in most high schools is very limited and inadequate, and most minor ailments are treated at home. Sometimes these treatments do not show proper improvement, but the boy does not complain or report any pain to the coach.

After a reasonable length of time, the injury may not heal properly and the boy may casually mention it to the coach, if he has not known about it before. Coaches then send the boy for medical treatment and x-ray. Some of these cases prove to be fractures rather than sprains.

Before each season a medical examination by a doctor is required. Why not the same after a football season? My face was very red when I sent three boys to be examined with finger injuries and all three proved to be fractures.

Conclusions

1. Treat all injuries as serious, until proven otherwise.
2. Recheck injuries and, where proper improvement is not shown, provide medical treatment and x-ray if necessary.
3. Provide a physical examination at the end of football season by a physician.

Dr. William E. Proffitt, formerly of the University of Minnesota football, basketball and boxing teams: I am very glad that Dr. Foster and Mr. Wells have invited me to discuss this subject. It represents a field of special interest to me, in that it ties together my previous athletic career and my present one in medicine and its application to the High School Athletic Program.

I feel very strongly about the points brought forth in the discussion because these boys in high school athletics have, in reality, the greater portion, not only of their life, but also of their athletic career, ahead of them. Also any injury they receive may be permanently hindering to their earning power in later years. I cannot see how anyone dealing with the health and safety of these young athletes can ignore "a sprain or strain" without an x-ray. I, for one, cannot see through the skin, muscles, et cetera as well as the x-ray can, and so I let the x-ray make my decision for me in all cases where an injury is incurred.

The present system of insurance as carried by the Minnesota State High School League, and very ably administered by Mr. Harold Peterson, is an excellent one. It protects the boy, the school, the system, and the doctor. Certainly there are some defects which, in time, can be remedied: The present red tape puts the burden of proof of injury, seeing that proper forms are obtained, filled out, and returned to the school involved, and the burden of treatment, all upon the doctor—all this within a short span of time. How much simpler and more to the point it would be to have the doctor have the necessary insurance blanks in his office, fill them out on the day of treatment, and send them in immediately to the State High School League, and have disposition made. Or the boy injured could bring the blanks with him on the first visit. I know that there would be much less confusion if this were done.

From my connections with athletics as a player and now as a doctor, I certainly thoroughly agree that even apparently minor injuries can be serious enough to need treatment, and that many fractures are undiagnosed. I am sure that Dr. Foster and Mr. Wells will be successful in their crusade to improve the quality of medical service given to these boys in high school athletics and still get them well rapidly enough not to lose too much time from their competition. This is, and I mean it, all-important to the participating athlete.

TRACHEOTOMY: INDICATIONS AND TECHNIQUE

ROBERT E. PRIEST, M.D.
Clinical Assistant Professor of Otolaryngology
University of Minnesota Medical School
Minneapolis, Minnesota

Indications

TRACHEOTOMY is indicated whenever one can be sure that the laryngeal airway is markedly obstructed and will not be reopened spontaneously if the disease is allowed to take its course (e.g., injuries and inflammation of larynx).

Tracheotomy is sometimes indicated in the absence of laryngeal obstruction when it is necessary to remove foreign material from the trachea or bronchi (e.g., vegetable foreign bodies, food and pharyngeal secretions in certain cases of bulbar poliomyelitis).

Good surgical judgment is necessary to decide whether tracheotomy needs to be done. In croup, the decision is difficult. In the cases seen early in one's experience, one is likely to be hasty about doing tracheotomy. The parents want the child treated in the safest manner, and one sometimes is hard put to know whether to operate or not.

If a child's color is reasonably good, although signs of narrowing of the laryngeal airway are present, the most important single index of danger is an increasing pulse rate. The pulse should be recorded frequently (every ten to thirty minutes). If the rate consistently rises, an impending circulatory failure is presaged, and tracheotomy should not be delayed.

The following complete list of indications is given by Thomson and Negus:

1. Injuries to the larynx—wounds and fractures of the laryngeal cartilages.
2. The extraction of foreign bodies when these are impacted in the larynx, or cannot be removed from the trachea or bronchi by the endolaryngeal route. The indication applies almost entirely to vegetable foreign bodies, which are liable to produce edematous swelling around the glottis.
3. Stenosis of the larynx or trachea,
   (a) External compression: goiter, aneurysm, mediastinal growths.
   (b) Internal constriction: inflammatory swelling, tuberculosis, syphilis, diphtheria, scleroma, neoplasms (carcinoma, papiloma, etc.).
   (c) Cicatricial narrowing, after healing of ulcers (syphilitic, typhoid, etc.) or operative measures.
   (d) Congenital webs in the larynx.
   (e) Double abductor paralysis.
4. (a) As a preliminary procedure to operations on the upper air passages, so as to prevent (by a tampon cannula or by plugging the larynx) the descent of blood into the bronchi. (b) Following these operations, to supply air to the patient.
5. In asphyxia, to allow artificial respiration.

Indications in Bulbar Poliomyelitis

In addition to the indications given by Thomson and Negus, as listed above, I wish to add those which resulted from our experiences in treating bulbar poliomyelitis patients during the Minneapolis epidemic of 1946. It was the opinion of the group involved that certain indications for tracheotomy exist in bulbar poliomyelitis patients. They may be summarized as follows:

In any patient whose bulbar symptoms are early and whose disease is progressing rapidly or who has evidence of involvement of the circulatory or respiratory centers or who has severe toxicity or mental changes, tracheotomy is indicated. In the patient whose bulbar poliomyelitis was severe enough so that the pharyngeal paralysis permitted spillage of secretion into the larynx and trachea, we advised tracheotomy only when the patient could not clear his own airway or when his airway could not be cleared for him by pharyngeal aspiration and postural drainage.

Inability of the patient to clear his own airway was indicated by recurrent cyanosis, coarse bubbling rales in the chest, laryngeal stridor and inability to cough efficiently. These symptoms are most important in excited patients who are unmanageable and in stuporous patients who are oblivious to the secretion running into their respiratory tree. Direct laryngoscopy may demonstrate pooling of mucus in the pharynx, paralysis of one or both cords, and diminished tactile sensitivity of the laryngeal mucosa.

The use of the respirator in bulbar poliomyelitis patients constitutes a further indication for tracheotomy. It has been the opinion of various authorities that the respirator is contra-indicated in bulbar poliomyelitis because the machine may

---

Dr. Priest is Clinical Assistant Professor of Otolaryngology, University of Minnesota Medical School: Chief Ear, Nose and Throat Service, Minneapolis General Hospital.

This paper was presented as a graduate course at the American Academy of Ophthalmology and Otolaryngology, Chicago, Illinois, October, 1947.

suck pharyngeal secretion down into the lower respiratory tract. Tracheotomy was used in several of our cases to permit aspiration of this material from the trachea and bronchi.

Types of Tracheotomy

Emergency.—Two emergency operations will be described. Both open the airway. One is actually a form of laryngotomy, and the other is a true tracheotomy.

1. *Laryngotomy, Intercricothyrotomy. — This operation has been condemned and with justification.* On the other hand, it may be life saving and there are certainly times when it is necessary. Its limitations must be understood.

A temporary opening into the airway is made by making a transverse incision through the cricothyroid membrane across the midline. The opening is maintained by improvised retractors (hairpins, etc.) only until a real tracheotomy can be done. Then the cricothyroid incision can be allowed to close

Continued use of this opening into the airway is wrong. The cannula will cause atrophy of the cricoid cartilage and make decannulation difficult by allowing the airway to collapse and by formation of scars within the larynx due to trauma.

2. *Emergency Tracheotomy.*—This procedure has been described so well by Dr. Chevalier Jackson that his description is quoted here:

Step 1. Throwing the trachea into prominence and fixing it in the midline are accomplished by pushing back the great vessels well under the sternomasted muscles. This is done in a second or two with the thumb and index finger of the left hand.

Step 2. Initial Incision.—With one sweep of the scalpel an incision is made from Adams apple almost to the suprasternal notch. This incision must go clear through the skin to facilitate free finger dissection. There may be considerable flow of blood but nothing immediately dangerous.

Step 3. Finger Dissection to Find the Trachea.—While the left thumb and middle finger are still holding back the great vessels under the sternomastoids the previously idle left index finger quickly locates the trachea by following downward from Adam's apple. The trachea is infallibly identified by the rigid character of its walls; there is nothing like it in that region. Every medical student has learned, or should have learned, the feel of it in the dissecting room. In identifying the trachea the finger at the same time bares its midline of tissue below the cricoid, by pushing the finger down under any overlying tissue; if the isthmus of the thyroid gland intervenes it is pushed downward and elevated. If it is torn or cut it will not matter. If an anomalous artery is felt crossing the trachea at this point it is pushed downward.

Step 4. Tracheal Incision.—The trachea having been identified and bared of tissue, the tip of the index finger is slid slightly to the operator's left side so that the scalpel in the right hand can be safely guided down along the palmar surface of the index finger onto the tracheal wall. Two or three rings are incised. In making the incision the middle finger of the right hand makes a guard against deep entrance of the knife that might otherwise go through the posterior tracheal wall into the esophagus.

Step 5. Holding Apart the Lips of the Tracheal Incision.—There is usually a hiss if the patient is breathing, but the lips of the tracheal incision in most cases lie so closely in contact that insufficient air is permitted to pass. The lips should be spread apart with a Trousseau dilator; if none is available a hemostat will do. Lacking these, the handle of the scalpel may be inserted in the slit and rotated slightly to cause gaping. Of course some blood will trickle into the trachea but cough will quickly expel it and spray it about. The cannula is inserted with its pilot; the pilot is removed if not blown out by the tussive blast. If by reason of deplorable lack of equipment no cannula is available someone must hold the lip of the tracheal incision apart until a cannula can be obtained or a makeshift devised for temporary use.

Step 6. Artificial respiration must be done if there has been respiratory arrest. Oxygen mixed with 7 per cent carbon dioxide should be liberated at the tracheal opening or gently insufflated through a catheter. The best cardiac stimulant is to get oxygen into the heart muscle by way of the circulating blood. No drug is a substitute for this.

Step 7. Hemostasis.—As soon as respiration is established hemostasis may be done in the usual way. If artificial respiration is necessary, temporary hemostasis may be afforded by packing gauze firmly into the wound and around the cannula.

Orderly or Tranquil Tracheotomy.—Conditions for orderly tracheotomy can be created by inserting a bronchoscope, Mosher life-saving tube, or endotracheal anesthesia tube through the stenotic larynx to provide a temporary airway. This airway is maintained by an assistant during the time tracheotomy is being carried out.

Technique.—Anesthesia for tracheotomy should almost always be local. In the hands of the occasional surgeon the rule should be that anesthesia ought always to be local. In rare instances where the tracheotomy is purely elective and when intratracheal anesthesia is available, general anesthesia may be properly considered.

At the University of Minnesota, our usual anesthetic is 1 per cent procaine with epinephrine infiltrated in the midline from the suprasternal notch to the thyroid notch. A rhomboid of injected anesthesia can be made to surround the field with no solution being injected in the midline. We have not used this method.

A midline incision is made from the thyroid notch above to the suprasternal notch below. The knife is carried through the skin and superficial fascia. Bleeding vessels are clamped. Tying may be deferred until just prior to opening the trachea.

Often cocaine is injected into the tracheal lumen just before the tracheal wall is incised The few moments necessary to allow it to produce anesthesia may be used to tie any skin bleeders still in need of ligature.

The midline incision is carried through the deep fascia. If the thyroid isthmus is broad and lies over the trachea where the tube is to be inserted, the isthmus should be divided and retracted to the sides. The division is carried out by dissecting the thyroid isthmus off the front of the trachea, clamping it and cutting between clamps. A running suture of fine plain catgut or silk is placed in each cut edge of the thyroid to control bleeding before the clamps are removed. Any large veins which interfere with proper placement of the tube are ligated and divided.

Some authors (Waldapfel) advocate a transverse incision of the fascia above the thyroid isthmus to free the isthmus, which may then be retracted downward and the tube properly placed without incision of the isthmus. No harm is done by division of the thyroid isthmus and the essential object is proper placement of the tracheotomy tube. At the University of Minnesota, we have practiced division of the thyroid isthmus whenever necessary.

After division of the thyroid isthmus, the tracheal rings can be seen through the thin fascia overlying them. The operator should reorient himself at this time. He should palpate the cricoid cartilage in the midline anteriorly and should count down to the third tracheal ring. *If there is any doubt in the operator's mind as to exactly where he should incise the trachea, he should take time to find out before he opens the trachea.* There is no more miserable or difficult problem than that of difficult decannulation, and this problem can only be avoided if the incision in the trachea is properly placed.

One or two cubic centimeters of 2 to 4 per cent cocaine solution are injected into the lumen of the trachea a few minutes before the incision into the tracheal wall is made. This makes the actual opening of the trachea quite a tranquil procedure, with little coughing and struggling on the part of the patient.

It has been our practice at the University of Minnesota to perform the punch operation of Mosher. A midline incision is made through the second, third or fourth rings, depending upon the accessibility of the trachea. An Allis forceps is then used to seize the tracheal cartilage through the incision, and a semilunar piece is removed from the anterior tracheal wall on the right and left sides of the incision. Mosher originally used a ring punch to remove the button of cartilage. Removal of a circular piece of the anterior tracheal wall permits easy insertion of tracheal cannulæ and prevents deformity of the tracheal cartilages by pressure from the cannula. The circular "button" or cartilage thus removed is about the size of the tracheotomy tube to be inserted. Another type of punch has been described by Waldapfel for removing this tissue, but we have had no experience with it. Before the trachea is opened a soft rubber urethral catheter is attached to the suction apparatus. This catheter is inserted into the trachea to aspirate blood or secretions.

The tracheotomy wound is not closed, and the only dressing applied is the gauze squares cut or perforated and placed around the tracheotomy tube. A tube is selected according to the patient's age and is inserted to a distance just proper to allow free breathing without danger of being dislodged. Care is taken not to allow a long tube to impinge on the anterior tracheal wall and thus produce cough, granulations or bleeding.

We have used the Jackson tubes made by Pilling exclusively because of their availability, proper curvature and generally satisfactory design.

The tape around the patient's neck is tied in a square knot (not a bow knot) and is preferably tied on one side rather than behind where the knot causes discomfort as the patient lies on his back.

Errors and Accidents Accompanying Tracheotomy

1. Too short an incision prolongs the operation and makes it more difficult. The incision is inconspicuous after it heals in most cases. Cosmetic surgery and safe surgery are not always compatible. The longer incision certainly makes tracheotomy safer by bringing all parts of the operative field into clear view.

2. After incision of skin and superficial fascia the next layer may not be separated in the midline and the operator may become disoriented.

3. The dome of the pleura may be punctured

as it bulges up into the wound, and pneumothorax may be induced.

4. The knife used to incise the trachea may be carried through the posterior wall of the trachea into the esophagus.

5. The cannula may fail to enter the tracheal lumen and may make a false passage outside the trachea. This is not as apt to occur if a "button" of the tracheal wall has been removed as described in the section on operative technique (Mosher's punch operation).

6. The operator may fail to identify the cricoid cartilage before he opens the trachea. This may lead to division of the cricoid and subsequently to laryngeal stenosis.

7. An improperly fitted tube causes erosion of structures pressed upon and may lead to various undesirable complications.

8. Entrance of blood into the trachea can be prevented by proper hemostasis unless there is urgent need for opening the trachea. If dyspnea is marked a small amount of bleeding can be ignored and the patient turned after insertion of the cannula so that the blood will not run into the trachea. The bleeding can be controlled later if it does not stop spontaneously.

Postoperative Complications

1. Emphysema of subcutaneous and fascial layers of neck occurs when air is forced into the tissues through the tracheotomy wound. Suturing of the wound favors the production of emphysema. Packing of the wound with vaseline gauze decreases the ease with which air is forced into the tissues. Some surgeons impregnate this gauze with sufonamide drugs.

Emphysema of the mediastinum has occurred in several of our cases at Minnesota but no serious result has ensued. Pneumothorax may follow emphysema of the mediastinum or may be produced by puncturing the dome of the pleura as it projects up into the neck wound. This complication is serious and must be dealt with by physicians accustomed to handling pneumothorax. Unless the pneumothorax is bilateral it usually is not a fatal complication.

2. Blood in the mediastinum was found at autopsy in one case but it was not definitely established that this was not a postmortem artifact.

3. Laryngeal or tracheal stenosis need not follow properly done tracheotomy.

4. Wound infections are rare particularly since antibiotic therapy and chemotherapy have been available.

5. Tracheitis usually follows tracheotomy. This is transitory. Excessive tracheal secretion is produced for a few days but after a week or ten days this decreases markedly.

Postoperative Care

Dr. Chevalier Jackson has emphasized in his writings that tracheotomy is not an object in itself. It is done to permit the patient to get air into his lungs. All the aftercare is directed at keeping the tracheotomy tube open and the wound clean.

When the patient goes to his room from the operating room, an exact duplicate of his tracheotomy tube is sent with him. It is most important that this tube be supplied with its own inner tube and obturator. Obturators and inner tubes usually fit only their own outer cannula. Lack of a proper obturator may be a very serious matter, if it delays changing of a tracheotomy tube. The extra tube is kept sterile on a tray with supplies for instant changing of the tracheotomy tube in case of emergency.

In addition to the tray containing the extra tube and its supplies, a general utility tray is provided. This holds the solution and materials for cleaning the inner cannula, as well as the suction tubing. The use of this tray will be discussed below.

Upon his return from the operating room, the patient is placed in a bed with the head elevated. The pillow is rubber covered. Water or portable machine suction is in the room at all times. The suction is so placed as to be instantly available for use in tracheal aspiration. The rubber catheter is always connected to the suction tube.

When the air of the patient's room is dry, it must be moistened to aid in the liquefaction of tracheal and bronchial secretions. Various methods of humidification have been employed. These include:

1. The patient's bedroom is rendered moist by cold humidifiers which spray a fine mist into the air by a centrifugal action.

2. A nebulizer may be connected to the tracheotomy tube and forcing of air or oxygen through the nebulizer from a tank of compressed gas, as described by Albers.

3. A centrifugal cold humidifier may be connected to an oxygen tent as advocated by Davison.

4. An atomizer spraying into an oxygen tent as described by Platou.

5. A moistened gauze sponge may be placed over the tracheotomy tube and may be replaced frequently.

6. Instillation of normal saline into the tracheotomy tube with a dropper. Proper precautions to prevent breakage of the dropper and entrance of glass into the trachea must be taken. The use of a short piece of rubber catheter on the end of the dropper minimizes the danger of glass fragments entering the trachea.

The patient is closely watched for hemorrhage and for closure of his tube by secretions or blood. The inner tube is suctioned frequently. When the rubber catheter is introduced into the tracheal cannula, the catheter is pinched shut until it has been inserted as far as necessary. This prevents the tip of the catheter from engaging the tracheal wall, or other tissue during introduction. Some surgeons instill normal saline into the trachea before tracheal aspiration is done. The saline loosens crusts and dilutes thick secretions. Some surgeons limit the extent to which the catheter can be inserted by the nurse by wrapping a collar of adhesive tape around it.

The inner cannula is changed every two to four hours, as ordered by the surgeon. It should not be left out of place for more than ten minutes at the longest. The outer tube is thoroughly sucked out before the inner tube is replaced. If this is not done, accumulated secretion is pushed into the trachea by the inner tube as it is introduced. The inner tube is cleaned by pushing a pipe cleaner through it. To clean an inner tube properly with an ordinary applicator is impossible.

The outer tube and the dressings are usually changed daily by the doctor, but some physicians change the outer tube at longer intervals.

CLEANSING OF TRACHEOTOMY TUBE

1. Rinse thoroughly with cold water.
2. Soak in sodium bicarbonate solution for one or two hours.
3. Cleanse, using special curved brush. These brushes come in various sizes. They may be obtained from the Pilling Company in Philadelphia.
4. Put on tie straps and boil for ten or fifteen minutes. Wrap with sterile towel and leave in patient's room at all times.

SPECIAL INSTRUCTIONS FOR NURSE IN IMMEDIATE CHARGE OF PATIENT

(Modified from Chevalier Jackson)

1. Read carefully all of above material pertaining to aftercare.
2. Wipe away secretions before they are drawn in by inspiration.
3. A patient with a properly fitting cannula free of secretions breathes quietly and noiselessly. Any sound demands immediate attention. Listen with ear close to cannula.
4. A patient with a tracheotomy tube often has no voice and cannot call for help.
5. Watch for loose parts on the cannula.
6. Watch color of lips, ears and face.
7. Report immediately if food or drink leaks through wound.
8. Never leave patient unwatched.
9. Remember that life depends on an open cannula if no air comes through the mouth or nose.
10. A baby's small cannula is plugged by only a little secretion.
11. Don't wear small children out by too much nursing care.

INSTRUMENTS NECESSARY FOR EMERGENCY TRACHEOTOMY

1 Scalpel, ordinary and pointed.
blades (Bard-Parker No. 10 and 11).
6 Hemostats.
1 Tracheal hook and spreader.
2 Allis forceps.
1 Tissue forceps (with teeth).
1 Dissecting scissors.
1 Suture scissors.
2 Small ribbon or rake retractors.
2 Suction tips—one metal and one rubber catheter about No. 12F.
1 5 c.c. syringe and needle for local anesthesia.
1 2 c.c. syringe and hypo needle for injection of cocaine into trachea.
1 Needle holder.
Needles.
Plain 000 tie.
Medicine glasses.
Gauze sponges.
Tracheotomy tubes—provide duplicates of size selected by surgeon.

SUPPLIES TO BE KEPT ON TRAY WITH TUBE IN PATIENT'S ROOM

Scissors for cutting gauze.
4–2 inch or 2.5 inch gauze squares.
Basin for saline used to clean wound.
Duplicate of tracheotomy tube worn by patient, complete with inner tube, obturator, and tape to tie around neck.

MATERIAL TO BE KEPT ON UTILITY TRAY

Basin holding about 250 c.c. 5 per cent sodium bicarbonate solution for washing inner and outer cannulæ.
Basin containing about 250 c.c. normal saline solution and two or three 2-inch gauze squares.
2 Robinson two-hole catheters (No. 14 and No. 16F), with ends cut off square and made smooth.
2 Old hemostats—general utility.
Emesis basin.

FUNDAMENTAL AND CLINICAL ASPECTS OF PULMONARY HYPERTENSION

CRAIG BORDEN, M.D.
Minneapolis, Minnesota

COURNAND and his co-workers, in 1941, developed the technique of venous catheterization of the right ventricle of the heart,[2] originally described by Forssmann,[7] to the point where it was adopted in many centers as a safe and important procedure for the investigation of circulatory dynamics in the intact human subject. The use of the Hamilton manometer in 1944 to record pressures optically through the catheter,[3] and the subsequent demonstration by Dexter that the pulmonary artery could be entered with safety and ease,[4] has permitted the accurate measurement of pulmonary arterial pressure in man.

A radio-opaque catheter is inserted into the median basilic vein of the arm and passed under direct fluoroscopic vision into the right atrium, right ventricle, and pulmonary artery. The catheter is kept patent with a slow continuous saline drip, to which it is connected by a three-way stopcock. The Hamilton manometer, which is connected to the catheter at the three-way stopcock by a short piece of lead tubing, is a rigid brass tube filled with air-free distilled water and closed at one end by an elastic metal membrane.[8] An attached mirror reflects a vertical light beam onto a recording camera. Pressure changes within the system cause slight motion of the membrane, attached mirror, and reflected light beam producing a pressure curve when photographed. The system is calibrated with an ordinary mercury manometer. Pressures are recorded at multiple points in the pulmonary artery, right ventricle, and right auricle as the catheter is slowly withdrawn. A respiratory tracing and one lead of the electrocardiogram are recorded simultaneously.

Though requiring special equipment and a trained team of three or four workers, the details of the technique are easily mastered with careful practice. The procedure is entirely safe in normal subjects and in selected patients with heart disease. Severe coronary artery disease, myocardial infarction, pulmonary infarction, and chronic or serious disturbances of rhythm are contraindications to the procedure. There is danger of air embolism in congenital cardiac defects with a shunt of blood from the right to the left ventricle of the heart, although small amounts of air entering the right ventricle from the saline drip are relatively innocuous if no shunt from the right ventricle to the systemic circulation exists. Patients undergoing venous catheterization experience no pain or undue discomfort. Local novocaine infiltration at the site of the skin incision over the antecubital vein employed for catheterization is the only anesthetic agent needed.

The systolic pressure is measured on the ventricular pulse curve to avoid artefacts which frequently occur in the pulmonary arterial curve due to "whip" of the catheter induced by ventricular ejection. The diastolic pressure in the pulmonary artery is measured on the pulmonary arterial curve at a point corresponding to the end of ventricular diastasis which is usually synchronous with the P wave of the electrocardiogram. Pressures are measured through a complete respiratory cycle from the peak of one inspiration to the peak of the next inspiration to take into account respiratory variation.

In twelve normal subjects, the average pressure in the pulmonary artery was 20.1 ± 3.7 mm. Hg. systolic and 8.8 ± 1.2 mm. Hg. diastolic with a normal range of from 11 to 26 mm. Hg. systolic and 5 to 11 mm. Hg. diastolic, respectively.[6] Pressures are relatively constant in any one individual and the normal range for the group is narrow. Factors, such as anxiety and exercise, which can greatly increase pulmonary blood flow, have little or no influence on the pulmonary arterial pressure in normal subjects. On the other hand, Hickam and Cargill[9] have recently shown that patients with congestive heart failure cannot increase their blood flow in response to exercise. The pulmonary arterial pressure in such patients is elevated at rest and shows a further marked elevation during exercise.

The following six disease states are implicated in the pathogenesis of pulmonary hypertension:

From the Veterans Administration Hospital and the Department of Internal Medicine, University of Minnesota, Minneapolis, Minnesota. Published with the permission of the Medical Director, Veterans Administration, who assumes no responsibility for the opinions expressed or conclusions drawn by the author.
Read at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 8, 1948.

1. Mitral stenosis and/or insufficiency.
2. Left ventricular failure from any cause.
3. Congenital cardiac defects where the shunt of blood is from left to right, particularly patent ductus arteriosus and interauricular septal defect, and occasionally Roger's disease. Eisenmenger's complex is also implicated.
4. Pericarditis, whether due to acute pericardial effusion or chronic constrictive pericarditis.
5. Certain cases of pulmonary emphysema.
6. Primary pulmonary arteriosclerosis.

In patients with mitral stenosis and dyspnea on exertion but without hepatomegalia or peripheral edema, there is a direct correlation between the degree of disability and the development of pulmonary hypertension. Patients with the findings of mitral stenosis who are asymptomatic have little or no elevation of pressure in the pulmonary artery, whereas patients with the symptoms of advanced mitral stenosis show elevations of pressure which can approximate or equal systemic arterial pressure. Such an elevation of pressure in the pulmonary artery carries a poor prognosis.

Patients with left ventricular failure due to hypertensive heart disease or aortic valvular disease show mild to moderate elevation of pressure in the pulmonary artery. There is no correlation between the degree of disability and the degree of pulmonary hypertension in left ventricular failure.

There is evidence to indicate that moderate or severe pulmonary hypertension is due in large part to increased resistance to flow through the pulmonary vascular bed and is not due entirely to back pressure from the left auricle. This is particularly true in mitral stenosis.

Excluding technical errors, a narrow pulse pressure in the pulmonary artery, with a systolic pressure which is distinctly lower than that in the right ventricle, is diagnostic of pulmonic stenosis.[5] The accurate diagnosis of pulmonic stenosis is of practical value in that it distinguishes the tetralogy of Fallot from Eisenmenger's complex. Such a distinction is obviously crucial in the proper selection of patients for the Blalock operation.[1]

Summary

1. The method of determining the pressure in the pulmonary artery has been briefly described.
2. The normal average value for the pulmonary arterial pressure has been defined as 20/9 mm. Hg.
3. The six disease states implicated in the pathogenesis of pulmonary hypertension have been listed.
4. The degree of pulmonary hypertension is an objective measure of the disability in mitral disease and is of value in prognosis.
5. The determination of pulmonary pressure is of practical value in congenital heart disease when the accurate diagnosis of pulmonic stenosis aids in the selection of patients for cardiac surgery.

In the treatment of pulmonary tuberculosis, complete bed rest is the foundation upon which the physician builds. In addition to this, collapse therapy of various kinds is used to provide local rest to some portions of the lung to initiate healing of the diseased process, to correct an unfavorable mechanical situation such as the presence of a cavity in the lung parenchyma, or to speed up the healing process. With the addition of collapse therapy, one may shorten the time of complete bed rest, allowing the patient to be ambulatory and return to a productive occupation at an earlier date.—Harold Guyon Trimble, M.D., *Am. Rev. Tuberc.*, May, 1948.

DISTURBANCES OF THE NAILS PRODUCED BY BASE COATS

CARL W. LAYMON, M.D., and ELMER M. RUSTEN, M.D.
Minneapolis, Minnesota

WITHIN the past few months physicians have observed a new disorder of the nails produced by base coats. There are several brands which are appiled directly to the nails beneath ordinary nail polish to prevent the latter from chipping and to reduce the frequency of application. Base coats have been on the market for several years, and in 1947 new formulas were introduced. Our attention was first called to reactions to the new base coats at a meeting of the Chicago Dermatological Society in March, 1948. Subsequently, at a meeting of the American Dermatological Association in April, 1948, the question of these peculiar changes was again considered. It was apparent that cases were being observed in various parts of the country. Positive patch tests were obtained in individuals so affected. Since these cases may be confused with psoriasis or mycotic infections of the nails, we thought that it would be of value to call the disorder to the attention of physicians in order that it might be recognized and these patients advised to discontinue the use of base coats.

Clinical Features

The clinical features of the changes produced by base coats are pathognomonic even though they vary in severity. One of the most striking changes is the discoloration, which may vary from magenta to different shades of brown. Generally the distal half is affected—occasionally the entire nail. The normal translucency is usually lost, although in two cases there was a waxy appearance. In most cases which we have seen, all of the fingernails have been involved, some more intensely than others. In addition to the discoloration, the nails are much drier than normal; they become brittle, and some present longitudinal striations. Onychauxis was observed in one patient. Another important feature is the deposition of hyperkeratotic material beneath the nail which leads to varying degrees of onycholysis. In most cases the latter is only partial and the nails are usually not shed, although they may become loosened. We saw one patient, however, in whom three finger nails were completely lost. We observed paronychia in one instance accompanied by pain, a feeling of numbness and diminution of the tactile sense.

Most cases which have been observed by physicians who are not acquainted with this disorder have been diagnosed psoriasis or onychomycosis. Although psoriasis of the nails may occur alone, it is most unusual, and concomitant lesions elsewhere on the body aid greatly in making a correct diagnosis. We have not observed the characteristic stippling in this disorder which is perhaps the most important characteristic of psoriasis of the nails. Neither have we seen the discoloration in psoriasis which is present in this disease.

Onychomycosis is characterized by a yellowish discoloration rather than the reddish-brown color present in this disorder. There may be loss of luster in both diseases. In mycotic infections, however, the nails as a rule become soft and crumbly, while in this disease they are hard, dry and brittle. In monilial infections, paronychia is a common complication, but it is apparently an unusual manifestation of disturbances produced by base coats. Culture of the involved nails aids in differential diagnosis.

Apparently the time required to produce changes in the nails by base coats varies greatly in different individuals. Most women who present these changes are unable to give an accurate history of onset because the manicurist applied colored enamel before the patient had a chance to examine the nails. Most of the patients whom we questioned stated that the base coat was used for several weeks or months before the discoloration was noted. It is our impression that once the process starts, progression is rapid. There has not been sufficient observation to formulate an exact prognosis, and undoubtedly the time required for the nails to return to normal depends to a great extent upon the amount of change produced before the base coat is discontinued. In one patient under our care, in whom only the distal halves of the

Fig. 3. Onycholysis of thumbnail and complete loss of nail of fourth finger.

nails were involved, there was steady improvement following discontinuance of the base coat, and within a period of six weeks the nails were almost normal. In another case all of the finger nails were involved in their entirety, and several were shed, and after eight weeks there has been but slight improvement.

Histologic Features

The histologic features of disturbances of the nails produced by base coats are reported through the courtesy of Dr. Louis H. Winer of Beverly Hills, California, who performed a biopsy on a characteristic case. Dr. Winer reported that the nail itself and the epidermis forming a cover for the upper portion of the tip of the finger showed no important pathologic changes. The epidermis of the proximal portion of the nail bed near the root of the nail, however, showed hyperkeratosis and vesicles containing nests of solidly packed, nucleated, keratinized epidermal cells. The nests of abnormal cells apparently forced the nail to become separated from its bed. Only the epidermis was apparent since the cutis was too thin and firmly attached to the bone to be included in the histologic section. Dr. Winer felt that the histologic picture was similar to that of contact dermatitis in other locations.

Experimental Applications

Patch tests with base coats offer an unusual problem in application and interpretation. The ideal test-area should be the fingernail or toenail. Multiple applications should be made, and some of the applications of base coat should be covered with nail enamel. Although glabrous skin may prove a suitable site for patch testing in this condition, too many of the procedures used in beauty parlors are omitted to make this method exactly comparable to patch testing in ordinary contact dermatitis.

Experimental applications of base coat and base coat plus enamel were applied to toenails of two patients at weekly intervals in an attempt to determine the time required to produce changes of the nails. Before each application the toenail was cleaned with polish remover. Both of the patients had disturbances of the fingernails produced by base coats.

Base coat alone produced changes of the toenail in five weeks; base coat and colored enamel, in three weeks. In both instances the first change was an amber discoloration at the lateral border of the nails, Paronychia developed in five weeks in the nail to which base coat and enamel had been applied. In ten weeks subungual hyperkeratosis developed in the same nail, and it had become completely discolored. This experiment suggested that the combination of base coat plus the occlusive covering of enamel produced changes more rapidly than the base coat alone.

Two patch tests with base coat on the anterior portion of the thigh were positive in seventy-two and ninety-six hours and remained for several days. Nail polish gave no reaction after twenty-four, forty-eight and seventy-two hours. The positive reactions of base coats did not extend beyond the site of application, thus resembling reactions produced by mechanical irritants.

Comment

Several questions arise in considering the pathogenesis of these changes of the nails. Is the substance producing the disturbances a primary

irritant, or is a process of hypersensitivity involved? Does the substance penetrate the nail plate, producing damage in the nail bed, or does it reach the nail bed from beneath the tip of the nail or at the base or lateral margins? Since the introduction of the newer base coats there have undoubtedly been many millions of applications, yet the reactions have apparently been relatively few.* For this reason it seems to us that the material must not be a primary irritant and that individuals who develop this type of disturbance must be hypersensitive to some ingredient in the base coat. Certain types of nails, because of their structure, thickness, fragility, or their chemical or allergic reactivity, may be predisposed to changes following the application of base coats. The disturbances vary in different nails of the same person and in different individuals. Even though most manicurists use caution to avoid application of substances beneath the nail it is impossible to avoid entirely their deposition under the free edge or beneath the cuticle at the base and lateral margins. Since we do not know the formulas of base coats, we cannot exclude the possibility that substances actually penetrate the nails, producing reactions in them and the subungual tissues. The positive reactions to patch tests with base coats in individuals who present these changes suggest that there is an actual contact dermatitis of the nail bed. The accumulation of hyperkeratotic material beneath the nail causes onycholysis and, in same cases, complete shedding of the nail. This report is preliminary, and considerable work is necessary before the problem can be completely appraised.

*One manufacturer alone reports the sale of more than 2,000,000 bottles, meaning 130,000,000 applications.

TRACHEOTOMY: INDICATIONS AND TECHNIQUE

(Continued from Page 1215)

Decannulation

This is accomplished in patients having properly performed tracheotomies by simple removal of the cannula after the patient has demonstrated his ability to breathe with the cannula closed for twenty-four to forty-eight hours. We have used rubber plugs whittled out of large rubber corks to close our cannulæ. It is important to use rubber stoppers, as fragments of ordinary cork may become pulmonary foreign bodies. These rubber stoppers should be secured to the tape encircling the patient's neck by a piece of thread 6 to 8 inches long. They are tethered by this thread when blown out of the tracheal tube if the patient coughs. In some cases half-round corks are used to partially occlude the lumen before full corking is done. Some surgeons use the obturator of the tracheotomy cannula as the stopper when trying out the patient's ability to get along with his tube occluded. We have not felt that this was quite as safe as the method outlined above.

Case Report

EARLY ACUTE BENIGN SYPHILITIC HEPATITIS WITH JAUNDICE

JOHN F. MADDEN, M.D.

Saint Paul, Minnesota

A case of early acute benign syphilitic hepatitis with jaundice is reported because of its rarity and because of suggestions for improving treatment. The example cited here is the only one recorded at the Ancker Hospital in Saint Paul.

Case Report

M. R., a white ward-maid, aged twenty-six, consulted her family physician February 18, 1947, because of a headache, a generalized eruption and jaundice. The patient stated that she noticed a vaginal discharge and dysuria about January 1, 1947. There had been numerous sexual exposures. A chancre was not found. She had a florid, generalized, macular secondary syphilide with mucous patches and patchy hair loss. A generalized superficial lymphadenitis was present, with the largest lymph nodes in the left inguinal region. The blood Wassermann reaction was strongly positive. She stated that jaundice appeared suddenly February 16, 1947. She was deeply jaundiced when admitted to Ancker Hospital on February 21, 1947. Severe headaches had been present for one week, and they were characterized by morning remissions and nocturnal exacerbations. The liver extended 1 inch below the costal margin, and the spleen was not palpable.

On February 21, the patient was put on a high caloric, low fat diet and given multivitamines. 50,000 units of aqueous penicillin were given intramuscularly every three hours.

On February 23, the jaundice was more intense and the liver and spleen were 2 inches below the costal margin.

The next day, the patient was nauseated and had anorexia. The penicillin was stopped, and 1 c.c. of bismuth subsalicylate in oil was given intramuscularly. This was continued at three-day intervals for nine weeks.

By February 27, the nausea and headache had disappeared, the liver and spleen were smaller and less tender.

On March 23, the liver was barely palpable, the spleen was not palpable, and the jaundice had decreased a great deal. 40,000 units of aqueous penicillin were started intramuscularly every three hours and continued until 4,800,000 units were given.

On July 1, the patient felt well, the jaundice had disappeared, the liver and spleen were not palpable, and all physical signs of syphilis had disappeared.

On September 6, the patient was asymptomatic and physically normal. The blood and spinal fluid Wassermann reactions were negative, and the other spinal fluid findings were normal.

ICTERUS INDEX CHANGES

Date	*Icterus Index*
2-25-47	165
3-1-47	200
3-6-47	225
3-9-47	150
3-14-47	83
3-25-47	42
4-1-47	30
8-8-47	7
12-20-47	5

Moore[2] stated that hepatitis of early syphilis occurs not more than once in 1,000 persons recently infected with syphilis. Stokes[4] observed only one undoubted case of early syphilitic hepatitis with jaundice in a survey of 300 patients with early syphilis. Wile[6] believed that the incidence was under 1 per cent.

The best working classification of syphilis of the liver seemed to be that of O'Leary[3] and his group. The classification follows: (1) early acute benign hepatitis, (2) syphilitic destructive hepatitis, or acute yellow atrophy, (3) subthreshold hepatic syphilis detected by functional tests, (4) hepatorecurrence, (5) mild chronic hepatitis of latent syphilis, (6) diffuse and localized gummatous hepatitis, (7) chronic interstitial pericellular cirrhosis of heredosyphilis and (8) perihepatitis.

Early acute benign hepatitis is a rare complication of the florid eruptive stage of syphilis. The chief symptom is jaundice, and the chief sign is enlargement of the liver. Stokes[4] stated that acute benign hepatitis of early syphilis is difficult to distinguish from intercurrent nonsyphilitic catarrhal jaundice and hepatorecurrence. Differentiation depends on (1) the presence of a chancre or secondary syphilitic eruption, (2) a Herxheimer reaction following treatment and (3) prompt cure if treatment is continued. Waugh[5] stated that there is no record of any patient with benign hepatitis of early syphilis coming to autopsy. Therefore, the pathologic condition of the liver has not been studied in this disease. The modern use of liver biopsy will enable workers to study pathologic changes in the liver.

Treatment for acute early benign syphilitic hepatitis with jaundice has been extensively discussed. Even though all authorities have thought that it was safe to use an arsphenamine preparation, there was a general feeling of uneasiness in doing so. Stokes[4] and others later advocated a combination of bismuth and arsenic. At present, it seems that the combined use of bismuth and penicillin is the most satisfactory treatment. The Herxheimer reaction and symptoms such as jaundice, anorexia and nausea can be controlled by decreasing or temporarily discontinuing penicillin when these signs and symptoms appear.

These reactions can be regulated even better by daily observation of the icterus index. Elliott and Todd[1] noted the value of observing the icterus index as early as 1928. The icterus index goes up before symptoms appear. If penicillin is stopped or the dose decreased, most unpleas-

History of Medicine In Minnesota

NOTES ON MEDICINE IN FREEBORN COUNTY, 1857—1900

ANDREW GULLIXSON, M.D.
Albert Lea, Minnesota

(Continued from October issue.)

Itinerants and Charlatans

The itinerant physicians that came with regularity were, as a rule, accepted and given office space by the local fraternity. These were, for the most part, high class men in their respective fields, and did very satisfactory work for their patients.

Charlatans came in numbers, advertising blatantly their lectures for men or for women only, or for special diseases. They usually stayed a few days only and left when exposed by the newspapers.

Physicians†

Dr. Albert Clark Wedge was a pioneer settler and for nearly fifty years was a leading physician in Freeborn County. He was a son of Rev. Albert and Elizabeth (Clark) Wedge and was born in Lewis County, New York, August 18, 1834. He descended from a family of Puritan stock, prominent in the early history of New England. Thomas Wedge, the founder of the family in America, settled in Litchfield, Connecticut, at an early day and five of his descendants were patriot soldiers in the Revolutionary War. The doctor's grandfather, Solomon Wedge, moved to New York state at the beginning of the nineteenth century and settled on a farm in Lewis County. He was a member of the New York militia and took part in the War of 1812. His sister married William Grant of Litchfield, Conn., a member of the family of ancestors of General U. S. Grant; and their son, Asahel Wedge Grant, was the first to respond to the call of the Congregational Society of Foreign Missions for a medical missionary to the Nestorians of Persia. He died at Mosul, Turkey, where he lies buried by the river Tigris, near the site of ancient Nineveh. Albert Wedge, the father of Dr. Wedge, was born in Connecticut in 1808, and was one of a family of eight children. He was educated for the ministry at Hamilton College, New York, and in 1839 moved with his family to southern Ohio, where he was engaged in missionary work. His wife died at Hillsboro, Ohio, in 1840, when the future Dr. Wedge was six years old. In 1847 the father moved with his five children to a farm near Pendelton, Madison County, Indiana. He died while on a visit to Wedge Prairie, Fond du Lac County, where his father and brothers were then residents. Together with his wife, he now rests in the family burial plot at that place.

After his father's death, the family was broken up and Dr. Wedge, aged seventeen, went to Wedge Prairie, Wisconsin, to live with his uncle. Here he attended school, worked on his father's farm, and taught in a country school. In 1854 he entered Ripon College and also studied medicine with Dr. J. Rogers at Ripon. Later he attended Cleveland, Ohio, Medical College, from which he was graduated in February, 1857. After graduation he returned to Wisconsin, expecting to locate at Ripon and practice with his preceptor. But his uncle, Lucius P.

†Physicians are listed chronologically, rather than alphabetically, as in previous histories.

Wedge, had been in Freeborn County and acquired property at Albert Lea and through his uncle's persuasion the young physician concluded to locate in Minnesota. His uncle supplied him with money, provisions, a span of horses, and a covered wagon; and in May, 1857, he drove to Albert Lea, which at that time consisted of a cluster of four or five log houses and about thirty inhabitants. To quote his own words:

"A few days after my arrival in May, 1857, I found the good lady of the cabin trying to feed the hungry men who were her boarders, with nothing to cook but flour, of which she made good bread and starch gravy. After a few days of this fare I concluded that I wanted a little change of diet, and so with the team I had driven from Wisconsin I made a trip to Mitchell, Iowa, to see if I could find something better. I found that we of Freeborn County were in a wilderness, yet here was a garden almost at our door."

He erected a frame building for his office and in July, 1857, the two-month-old newspaper, *The Southern Minnesota Star,* carried the modest card, "Dr. A. C. Wedge, Physician and Surgeon." His clientele was meager and the panic of 1857, with repudiation of currency, brought forth barter as a means of trade. In November, 1857, he performed his first amputation, a double amputation of the feet, necessitated by freezing. This patient died in February, 1858, and became the first case to be entered and adjudicated in the office of Judge of Probate in Freeborn County. In this operation he was assisted by a Dr. Charles S. Tarbell of Shellrock. Dr. Wedge filed a claim for $100 for his service in the case, and this was allowed in full, including ten bushels of corn. Dr. Wedge filed on lands under the recently passed pre-emption laws, equipped a drug store, and proceeded to take an active part in building up the community. He was elected chairman of the first Board of County Commissioners when the county was organized in 1858. In October, 1859, he married Miss Betsy Blackmer, a sister of Dr. Frank A. Blackmer. They had one child, a daughter, who died in 1905, leaving a son, Albert Wedge Jones. He, succeeding his father, Mark Jones, now conducts a successful insurance business at Albert Lea.

Dr. Wedge enlisted for military service in May, 1862; was commissioned assistant surgeon to the Third Minnesota Volunteer Infantry Regiment and joined his command at Murphreesburro, Tennessee, the same month. On July 13 he participated in the battle of Murphreesboro, in which his regiment was surrendered to the enemy by the colonel in command. Dr. Wedge was ordered to duty in the hospital and later was ordered to Nashville, Tennessee, where he was on duty in the general hospital for several months. His regiment was then exchanged, and he joined it again at Cairo, where it took part in the campaign through Kentucky and Tennessee, joining General Grant's main army at the investment of Vicksburg. In September, 1863, he was commissioned surgeon with the rank of major. He was with General Steel's forces in the expedition to capture Little Rock, and in all the battles connected with the campaign in Arkansas during 1864 and 1865. Together with his regiment, he was mustered out of the service in September, 1865, at Devil's Bluff, Arkansas.

Dr. Wedge was at all times very efficient and faithful as a surgeon and had the fullest confidence of all the officers and men to whom he ministered. He performed especially notable service for the Third Regiment during its stay at Pine Bluff in the spring and summer of 1864. The regiment was then encamped in a swampy, unhealthy locality, and a violent epidemic of malaria broke out. The result was disastrous. A large majority of his command was stricken. From May to August 150 died. The doctor labored incessantly and without adequate medical supplies and, when at last he became infected, no quinine could be

obtained (*Freeborn County History,* 1911). After returning to Minnesota, he resumed active practice, took the place of leadership in civic affairs, and became especially active in Republican politics in the state. He served in the lower house of the state legislature in 1870 and 1871, and was the chairman of the committees on railroad and state prison investigation.

In a vest pocket diary and account book which he kept through 1870 and 1871, the following entries occur:

"Jan. 1, 1870, draw out of bank $50.00, start for St. Paul; arrive at Ramsey 11½; arrive at Park Place 8:00 P.M.; rather a pleasant day. Sunday, Jan. 2, '70, attend church in the evening; heard Rev. Mr. White. Day very pleasant. Monday, Jan. 3, '70, a lively day, caucus this evening. Tuesday, Jan. 4, '70, House organized today. Wednesday, Jan. 5, attend the Grand Lodge this afternoon. Cold damp wind making it rather unpleasant. Friday, Jan. 7, House adjourned to Tuesday next. Governor and State Officers sworn in today. A stormy day, snow and cold. Saturday, Jan. 8, arrive home at 2½ a.m., find everything lovely. January 9, a stormy morning but pleasant. Amputate leg for Mr. C—. Attend church in the evening. Tuesday, Jan. 11, House meets at 2:00 p.m. No business of importance. Transact some business in state treasurer's office. Sunday,. Jan. 16, snow and rain. Very unpleasant. Attend church, hear Rev. Mr. A—; make some calls in the evening. Monday, Jan. 17, a cold northwest storm, so much snow in the air we cannot see; rail cars do not go. Jan. 18, do not get away because of snow."

During the campaign for state senator in 1879, he was opposed by the temperance people. On one occasion he said, "I do not care for the temperance voters and I hope those voters will remember that on election day." But he introduced a bill in the legislature, which was passed, granting county supervisors the power to license and restrain the sale of liquor. He sponsored a bill to set aside internal improvement lands for payment of the old railroad bonds. Later, when these bonds were declared fraudulent and were repudiated by the signature of the governor, Dr. Wedge, with his sterling honesty, remarked: "Any one who votes to repudiate these bonds is a dishonest man."

In the legislative session of 1879-1880, he served on the committees of the state university and university lands and of education and railroads. He resigned as senator in 1881, to accept the appointment as District Collector of Internal Revenue, with office moved to Albert Lea. He was a delegate to about every Republican county and state convention, and to the Republican national convention in 1880, when President Garfield was nominated. He served as Assistant Surgeon General on the staff of both Governors Merriam and Nelson. In 1883 he served, under the governor's appointment, as a member of the State Board of Medical Examiners and Licensers, and for one year was chairman of the board. After the laws were revised in 1887, he also served as a member for many years. In 1878, as a delegate to the State Medical Association's meeting, he served on the executive committee and also as chairman of the committee on surgery. In the October, 1879, meeting, he was chosen president of the State Medical Association and it was decided that the meeting in 1880 should be held at Albert Lea. In 1878 he was appointed on a committee including Dr. Frank Blackmer, to draw up articles of incorporation for the village of Albert Lea. In 1861 he and Dr. A. M. Burnham were the medical representatives on the staff of executioners at the one and only legal hanging in Albert Lea. In 1888 he was chosen vice chairman of the Freeborn County Anti-Horse Thief Asociation, comprising a captain and sixty vigilantes "organized and ready for business." In 1857 he was instrumental in organizing the first lyceum, under the inspiring name, "The Albert Lea Senate." In 1885 he was chairman of the committee on organization of the Freeborn County

Agricultural Association and County Fair. "No citizen leads Dr. Wedge in enterprise and plans for progress of the people. He provides the fair grounds, including a fast racetrack, for the first County Fair."—*Standard,* 1885.

In 1887 he delivered lectures on physiology to classes at the Presbyterian Ladies' College. In 1889 he was included in Governor Merriam's party to the centennial celebration in New York City. He met and visited with President Harrison, Secretary Windom, Generals Sherman and Schofield, Admiral Porter, and other dignitaries. In October, 1892, he, as a member of the governor's staff, attended the dedication services on Columbus day at Chicago World's Fair. In July, 1890, final articles of incorporation of Freeborn County Agricultural Association were drafted and were signed by Dr. Wedge among the first on the committee. In May, 1896, he was chosen vice president of the National Association of Railway Surgeons. In 1898 the Society of Territorial Pioneers was organized in his office with Dr. Frank Blackmer as historian. In the same year Dr. Wedge was instrumental in organizing the Albert Lea District Medical Association, comprising physicians from Freeborn County and from Worth and Winnebago Counties in Iowa. Dr. Wedge was chosen temporary chairman, and later chairman, of the permanent organization. Twenty-six physicians joined at the first meeting. In 1903 at the organization of the Freeborn County Medical Society, Dr. Wedge was chosen its first president. He was in regular attendance at county and state medical meetings and frequently in attendance at the national meetings. He was a busy physician and surgeon, and charged small fees, as was the practice in those days. In a day book dated 1873, appear the following entries for March:

"C— to visit wife at night, $1.50; Mr. R— to visit wife and self $1.00; L— to visit (6 miles) and medicine self $4.00; Mr. W— to call and advice for self $1.00; J— to visit baby $1.00; Mr. A— Obst. wife $10.00. February 3, 1873, to obstetrics and forceps $20.00; consultation Dr. Froshaug, office, amputation toe $5.00."

Aside from his farming and political interests, his hobby was the raising and breeding of thoroughbred shorthorn cattle. In this he performed a great service to the county by building up a better quality of livestock. He raised and bred good trotting horses and attended the trotting races regularly. A long time hobby of his was to serve as helper, adviser, and pensioner for old indigent horsemen. Even until his last years they would come to him for the needed help and comradeship and would depart with the usual $10.00 or $20.00. His sterling worth as a man of prominence in the state and his standing and ability as a physician and surgeon have been subjects of various articles in the press and medical journals, and merit remembrance. The least that we can do in honor of this kindly distinguished gentleman is to call to mind his lifelong service to this community.

Nature gave him a sound mind in a sound body, and he needed both to accomplish what he did under the pioneer conditions of life in the region in which he chose to apply his talents and serve his fellow men. He needed courage, he needed ability, and he needed good will; and he possessed them all in abundance. He died October 23, 1911, at the age of 77 years. "At his funeral, business throughout the city was suspended at the order of the mayor, and thousands followed in sorrowing concourse to the grave."—*Standard,* October, 1911. Providence was kind to Freeborn County in providing this true physician and counselor, Dr. A. C. Wedge.

Dr. Franklin Blackmer was born in Allegheny County, New York, June 10, 1804. Choosing medicine as his profession, he no doubt read with able preceptors and was graduated. He practiced in Amherst, Ohio, from 1831 to 1856.

He married Miss Minerva Wilkins in 1833. He came direct to Minnesota in 1856 and settled on land adjoining Fountain Lake, at Albert Lea. One son, Dr. Frank, and one daughter, Betsy, who became the wife of Dr. Wedge, were the only children.

Dr. Franklin Blackmer was recognized as a well-read physician and was highly respected as one of the first settlers. He never engaged in the practice of medicine here in Freeborn County. His death in 1877 was keenly mourned by the old settlers, who shared with him the hardships incident to the new country.

Dr. George Watson was the first senator to represent Freeborn County in the state legislature. He served from 1858 to 1862. By provisions adopted at the constitutional convention in 1858, the representative boundries were changed and Freeborn became attached to Faribault County, forming the fourteenth senatorial district. Dr. Watson was elected senator from this district in 1858 and served until 1860. In 1860 another change was made, connecting Freeborn with Steele and Waseca counties, forming the sixteenth senatorial district. Dr. Watson was again sent to the Senate and served until 1862.

Not much is known of Dr. Watson except that he was a politician. His home was in Sumner village, Moscow Township, which became an historical landmark years ago.

After his service as senator (1858-1862), Dr. Watson moved to St. Paul, where he secured a government position as chief clerk in the surveyor's office, a position he held for about fifty years. He was always referred to as "Doctor" but there is no evidence that he ever practiced medicine (*Freeborn County History,* 1882).

Dr. Charles S. Tarbell was located at Shellrock in 1857. The *Freeborn County History,* 1882, refers to C. S. Tarbell as coroner, 1857-1858. The only record that would indicate that he practiced medicine was found in the files of the probate court, in which he filed a claim for forty dollars as a fee for assisting Dr. Wedge in performing a double amputation in November, 1857. The claim was not allowed in full but was reduced to thirty dollars, ten of which was paid with ten bushels of corn in November, 1859. He evidently did practice at Shellrock at that time but left during the war.

In 1857 a newspaper notice refers to a **Dr. Yates,** located in Riceland Township, but nothing further is known of him.

Dr. Alfred Mark Burnham was born in Genisee County, New York, October 16, 1825, and received his early education there. He attended the public schools, Bethany Academy, and the schools at Springville and Centerville. He read medicine with Drs. Steward and Farmer, finally entering the University of Buffalo and graduating from the department of medicine in 1853. He came to Freeborn County in 1857 and settled on land which he named Paradise Prairie and which later contained the townsite of Itasca.

His first winter was spent at Shellrock (Glenville), where he built a hotel, and on a contract for $244 constructed the first bridge across Shellrock River. Later he constructed a steam-propelled boat called the Itasca, on which he transported lumber and logs (no doubt from government lands) up the Shellrock River, Lake Albert Lea, and on up to his town-site, Itasca, on Paradise Prairie. Itasca soon claimed a hotel, a blacksmith shop, a shoemaker shop, a drugstore, a newspaper, and a dozen houses. The purpose of all this was to secure for Itasca the dignified status of county seat.

In the guerrilla warfare with Albert Lea that followed, Itasca lost, and soon passed into oblivion. A couple of instances may be mentioned. Itasca followers with Dr. Burnham executed a $6,000 bond, pledging to build a court house of brick, to be completed in two years. Albert Lea followers with Dr. Wedge executed a $5,000 bond, pledging to furnish a court house and jail free of all cost to the county. Dr. Burnham had acquired the ownership of the hotel at Bancroft on the authority of a dollar and thirty-five cent tax certificate. This he moved to Itasca by two strings of ten ox teams, each led by a team of horses. At the same time a Presbyterian minister came to Albert Lea and was very enthusiastic about building up institutions in the interests of his denomination. The Albert Lea group (with the able assistance of Dr. Wedge no doubt) sensed his enterprising spirit and suggested to him that the hotel at Itasca would be a splendid suburban location for such a school. The minister approached Dr. Burnham, who, delighted with the idea and being anxious to do what he could to aid in the work, was willing and ready to sell the hotel. The transfer was made, the Albert Lea proprietors paying for it. It was then torn down and moved to the county seat. The scheme having served its purpose, no more money was advanced; and the ardent proponent of Itasca as a school-site moved on to some more promising locality.

It is difficult to determine the amount of time Dr. Burnham devoted to the practice of medicine. At divers times his speculative ventures took him far afield.

"Dr. Burnham, of Itasca fame, discovered another gold mine five miles west of Ft. Saunders; specimens are encouraging."—*Frontier Index,* Ft. Saunders, Dakota, February 20, 1866.

"Dr. Burnham, the inimitable, reports he has a grain sack full of greenbacks acquired while under contract with the Union Pacific Railroad for cutting railroad ties in Wyoming Territory."—*Standard,* 1869.

An article by Ida Picket Bell, titled "Pioneer Family Life at Itasca," states:

"Another boomer was Dr. Alfred Burnham, a bright reckless young physician, who came from Buffalo with his young wife. He gathered around him a bunch of adventurers, and there were wild stories about them, which were probably much overdrawn but which surely had some foundation in fact. His wife was a darling and was beautiful, but the kind of men she had to live with made her do some strange things. She would either have to do that or sink under the current. But she was not the sinking kind. My mother found her to be a warm-hearted, helpful friend and we children learned to love Aunt Russia. She died childless, June 7, 1865, and lies buried in a lonely little graveyard on Paradise Prairie."—*Albert Lea Tribune,* November 7, 1932.

Dr. Burnham enlisted in the Tenth Minnesota Regiment, October 11, 1862. He was discharged on special order, on a peoples' petition in October, 1863.

"We are informed that Dr. Burnham of Itasca is scattering his money with a lavish hand. He is remodeling his dwelling, also repairing farm buildings, building barns and granaries and erecting several miles of fence."—*Standard,* June, 1871.

"Dr. Burnham is getting a good deal of practice already. The doctor has many friends and will have a large practice when people know that he is available."—*Standard,* February, 1880.

"Dr. Burnham, together with Dr. Frank Blackmer, shipped six carloads of cows to Laramie, Wyoming. Dr. Blackmer will spend the winter in Denver and Dr. Burnham will go to the West Coast with his family, having disposed of all his properties here."—*Enterprise,* January, 1884.

"In a letter he writes as follows: 'Sold cattle and horses same day; bought ticket to Portland; got into cars 9:00 P.M., dog, parrot, children, wife with three saratogas and self in black dog skin coat. Arrived at Portland seventh day. Took in town of Portland by riding every street car to the end. Fine town, lots of business. Took boat forty miles, then via Northern Pacific to Tacoma. Rest a day, rent house which cost three hundred dollars, at

sixteen dollars per month. Ships coming and going, streets full of strangers, one hundred stores, one thousand buildings under way, large hotel and school house, fine teachers and books. Business enough here for me. Inhabitants American entire and all like a mess of maggots. I have come home.'"—*Enterprise,* March, 1884.

In 1886 Dr. Burnham moved to the coast and finally accomplished his heart's desire in founding the town-site of Gig Harbor, Washington. Dr. Burnham's second wife was Miss Hord. To this union four children were born: Lulu S., Frank M., Clarence S., and Alley.

"The many friends of Dr. Burnham, who was a conspicious figure in pioneer days of Freeborn County, will regret to learn of his death at Gig Harbor, Wash., July 11, 1896. He was one of the biggest-hearted men that ever lived and was admired for his sterling qualities. He was bluff and outspoken, but a kind-hearted, generous man, a good husband and father." —*Enterprise,* July 16, 1896.

Dr. J. K. Moore.—A short paragraph in Freeborn County History, 1874, states that in 1861 J. K. Moore came to Freeborn village and offered his services as the first physician in that village. He evidently left very soon, as no record is found of his continuing practice there.

Dr. Elizabeth (Heath) Stacey, wife of Judge E. C. Stacey, was born at Pike, Allegheny County, New York, October 4, 1817. She died at Albert Lea, December 19, 1896, in her ninetieth year. She came with her husband to Freeborn County in June, 1856, locating at Geneva. It is told that she named Geneva and the adjoining beautiful Geneva Lake. In December, 1859, Doctor and Judge Stacey, together with their children, moved to Albert Lea, where the family resided until the father and mother died. In 1840, at the age of twenty-three, Dr. Stacey was united in marriage to Judge Stacey, son of the noted Nathaniel Stacey of the Universalist Church. For a number of years thereafter, the family resided at Columbus, Warren County, Pennsylvania, until they came to Minnesota in 1856. Four children, one daughter and three sons, were born to this union: Dorr, Day, Lynn, and Lizzie. The last two died early in life. Judge Stacey died in April, 1897. Dr. Stacey, a brilliant student and teacher, was a remarkable woman of unusual strength of character. She was a practicing physician for many years, especially during the Civil War. She attended many obstetrical cases during those years. She was said to be the first woman physician to graduate from the University of Michigan Medical School and the first regular woman physician to practice in Minnesota.

She was faithful both to the responsibilities of her calling and to those of her household, and considerate toward her neighbors and their welfare and happiness. She was an ardent temperance worker and held high places for many years in the councils of the Good Templars. She traveled a great deal in the 1870's and 1880's, both in this country and abroad, including Mexico, Alaska, Europe, Egypt, and Palestine. She was an ardent worker and worshipper in the Universalist Church, to which she freely gave of her counsel and her means. She died after a brief but "acute attack of stomach trouble," December 19, 1896 (*Standard,* December, 1896).

It is a pleasure to bring to light the memory of this aristocrat, this patriotic pioneer physician and philanthropist.

(To be continued in the December issue.)

President's Letter

"LICENSE TO PRACTICE"

William Osler, the renowned professor of clinical medicine, had just returned to the United States after a wedding trip to England and was being entertained at the Minnesota Club one October evening in 1892 by members of the Minnesota Academy of Medicine. After dinner the guests adjourned to the House of Representatives in the old State Capitol where he then spoke on "License to Practice." A summary of this address, as well as of the subsequent history of medical licensure in Minnesota, is presented in the July issue of MINNESOTA MEDICINE, and I commend it to all members of the State Association as worth-while and informative reading.

The entire article sets forth the principles of practice which form the main points of the law as it exists today, as recorded in MSA 147.02 under the heading of "Examination and License; revocation." Nine specific rules are listed, defining the limits of "immoral, dishonorable or unprofessional conduct." It would be well for everyone to refresh his acquaintance with his minimum professional obligations as set forth in these nine rules.

It is, of course, impossible to comment on each of these in this brief letter. Consciously or otherwise, all of you are acquainted with them. The one, however, which bears particular emphasis at this time is No. 9, and reads, "Conduct unbecoming a person licensed to practice medicine or detrimental to the best interests of the public." Although the occasions when the board has found it necessary to enforce this particular point are rare, I am sorry to say that some such situations have occurred.

Will anyone disagree that privileges granted the practicing physician by his license also impose upon him a strong obligation to behave in a manner thoroughly becoming the intent of rule No. 9? Right now certain types of medical testimony are causing great concern to our State Association. Nothing ranks higher than truth, and it is imperative that medicine always be on a high plane, not only in the hospitals and in daily practice, but also in its relation to other professional groups. By the same token there is no room for professional jealousy, if medical practice is to continue in high respect. There is no reason for ever hearing the phrase, "Well, Dr. Jones and Dr. Smith just do not get along with each other." I am sorry to say that instances have arisen when the Board of Medical Examiners has been sorely pressed to avoid punitive action suggested by the attitude of one physician toward another.

Ours is a profession which should be always above petty jealousies, not only for the sake of the patient and of medical progress *but for our own sakes.* Does anyone think for a moment that actions within our membership which reflect adversely upon the profession do not suggest to our customers—the lay public—that our job could be done better under government direction? Let's keep first and foremost in mind the fact that public opinion in this, as in other respects, must be served through a full sense of responsibility which seeks to avoid petty quarrels and jealousies and actions which are unbecoming and in clear violation of accepted rules. Try as we doctors may, we shall not succeed in building public good will—we shall not have the public fighting on our side—if the nature of the everyday conduct of *any one of us* leads the public to believe that its welfare is not being best served because of our poor judgment and poor professional manners.

The history of licensure in Minnesota reveals that it has steadily encouraged the highest standards of practice in medicine. We physicians must strive in every way to maintain that high level of service and never allow ourselves to be guilty of conduct which may overstep the privilege inherent in our license to practice, and thereby incur costly public disfavor.

President, Minnesota State Medical Association

BLUE CROSS AND BLUE SHIELD CONSOLIDATION

AS we go to press, a meeting of the National Blue Cross and National Blue Shield associations, the former composed of the state voluntary prepayment hospital insurance organizations and the latter made up of the state prepayment medical insurance organizations, is about to be held (October 25) at French Lick Springs, Indiana, for the purpose of consolidating the two into a national hospital and medical care insurance organization, to be known as the Blue Cross-Blue Shield Health Service, Inc.

A brochure approved August 20, 1948, by the combined Blue Cross and Blue Shield commissions sets forth the reasons for the amalgamation of the two organizations. The fear that the government will establish a compulsory insurance plan such as that embodied in the oft-proposed Wagner-Murray-Dingell Bill, and the contention that industries operating on a national scale require a national health service, are two of the main reasons given in the brochure for the necessity of the amalgamation. The brochure was sent to the state Blue Cross and Blue Shield organizations, but the various state medical associations had to ask for them in order to know what was in the offing. The meeting was planned without consulting the national or state medical associations as to their approval. As it was through the help, financial and otherwise, of the AMA that the national organization of the Blue Shield state associations was formed, this oversight seems rather inexcusable.

To give a better understanding of the attitude of the physicians of the country to the proposed amalgamation the following events are mentioned.

At a meeting of the presidents of the state medical associations held June 19, action was taken that further study of the proposal to form a national Blue Cross-Blue Shield organization be made by the Council on Medical Service of the AMA and that no such national insurance organization be formed at that time. This recommendation was approved by the AMA House of Delegates shortly thereafter.

On October 2, 1948, after the brochure had appeared, the Council on Medical Services of the AMA unanimously refused to approve the proposed amalgamation, and on the same day the AMA Board of Trustees unanimously endorsed the action of the Council. The state medical associations were notified of the action taken by the Council and the Board of Trustees.

In view of the apparent overwhelming opposition to the proposal on the part of the profession, it scarcely seems possible that the proposal will be carried through on October 25. While the Minnesota Blue Shield plan is separate from the Minnesota State Medical Association, it was brought forth by the State Association, and several councilors of the State Association are on its Board of Directors. This places these Councilors in a delicate position to say the least.

We cannot go into the pros and cons of the proposed consolidation of the associated Blue Cross and Blue Shield organizations. The arguments of the proponents that it is a necessary step to prevent the federal government from establishing a compulsory insurance program does not appeal to us. The proposed Blue Cross-Blue Shield Health Service resembles too closely the proposed governmental plan. Its overhead would be tremendous, and if it went in the red, what an opportunity for the government to step in. Certainly, too, ways could be devised for insuring employes of national industries in individual state Blue Cross and Blue Shield organizations or separate national Blue Cross and Blue Shield associations.

Certainly the unanimous opposition of the members of the Council on Medical Service and the Board of Trustees of the AMA, who doubtless studied the proposition, means much. If the AMA House of Delegates had been given the opportunity to act on the present proposal, it undoubtedly would have voiced its opposition. The meeting of October 25 suggests the enthusiasm

and premature action of a few in a matter which requires more deliberation.

The Oregon State Medical Association has been following these events with remarkable zeal and has publicized their sequence and taken a firm stand against the amalgamation. According to the latest news a civil suit has been filed by the Federal Department of Justice against the Oregon State Medical Association, the Oregon Physicians Service, eight county medical societies and eight individual doctors, charging them with violation of the Sherman anti-trust act in conspiring to deprive the public of the opportunity to acquire prepaid medical care insurance from other sources. The suit is obviously a test case. On the outcome of the suit the status of the other state Blue Shield organizations will be determined.

BULLETIN OF THE UNIVERSITY OF MINNESOTA HOSPITALS AND THE MINNESOTA MEDICAL FOUNDATION

EACH member of the Minnesota State Medical Association has been sent a copy of the *Bulletin of the University of Minnesota Hospitals and the Minnesota Medical Foundation.* Membership in the Foundation will automatically bring copies of the *Bulletin,* which is published weekly during the school year and contains full reports of the University Hospital weekly staff conferences, a calendar of events at the medical school and news of special activities in the medical school and among its alumni.

The Minnesota Medical Foundation was established in 1940 and in its eight years of existence has collected more than $90,000 and disbursed about $50,000 in the support of worthy projects such as promoting medical education and research, and in assisting worthy students. Annual dues are $10 and life membership $100. Bequests in larger amounts for specific research projects may also be made. Requests for further information may be addressed to The Minnesota Medical Foundation, 132 Medical Science Building, University of Minnesota, Minneapolis 14. Checks should be made payable to the Minnesota Medical Foundation, and donations are deductible in both federal and state income tax returns.

The Foundation has just established a lectureship at the Medical School as a memorial to the late Dr. Jennings C. Litzenberg, professor of obstetrics and gynecology for many years, who died August 15, 1948, at the age of seventy-eight. A native of Waubeek, Iowa, Dr. Litzenberg obtained his medical degree at the University of Minnesota in 1899. While still a medical student he became an assistant to Dr. L. J. Cooke, the University's physical training director, which position he held for nine years after his graduation. He then specialized and supplemented his education with studies in Vienna, Berlin, London, Glasgow, and Dublin. He headed the department of obstetrics and gynecology from 1914 until his retirement in 1938 to the status of professor emeritus.

WANTED: UNKNOWN DIABETICS

PHYSICIANS will be interested in a national broadcast entitled "Wanted: Unknown Diabetics" which will be one of the 1949 winter series of AMA-NBC broadcasts, sponsored by the AMA, entitled "Your Health Today."

It is estimated that there are about 2,400,000 unknown diabetics in the country today and the broadcast is part of a program of publicity planned for National Diabetes Week which will endeavor to call attention to premonitory warnings and early signs of diabetes.

Featured speakers on the AMA program will be Dr. Elliott P. Joslin and Dr. Howard F. Root of Boston; Dr. Charles H. Best of Toronto; Dr. Lester J. Palmer of Seattle, western vice president of The American Diabetes Association. A patient who has successfully coped with diabetes for more than twenty-five years and remains in excellent health will also take part in the program.

Included in the program will be a memorial tribute to Sir Frederick Banting who, with Dr. Best, discovered insulin and made the control of diabetes possible.

The broadcast will be supervised by Dr. W. W. Bauer of the AMA Bureau of Health Education, and Miss Judith C. Waller of NBC.

The appearance of tubercle bacilli in sputum, gastric contents or other body fluids is an extremely significant episode in the course of tuberculous infection. Hence, a thorough and systematic search for tubercle bacilli must be instituted in all cases where the presence of tuberculosis is suspected or where tuberculosis must be considered a possibility in differential diagnosis.—Francis J. Weber, M.D., *Pub. Health Rep.,* Sept. 3, 1948.

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

MR. EWING PUTS HEALTH ON THE ASSEMBLY LINE

Given four billion dollars in tax money, Oscar Ewing, Federal Security administrator, promises to save the lives of 325,000 persons each year, as well as to assure vastly improved standards of health for everyone, "regardless of race, color, creed or income."

His "Ten-Year Program," which he presents as a report to the President, has appeared in published form and only during a political campaign could so many grandiose promises be had for so little (one dollar, sent to the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C.).

Since Mr. Ewing opens his brochure with the statement that "every year, 325,000 people die whom we have the knowledge and the skills to save," it is well to begin an analysis of his health program at that point. He breaks down this figure into these component parts: communicable diseases, 120,000; cancer and heart disease, 115,000; accidents, 40,000; infant and maternal, 30,000; other, 20,000. The administrator's answer to this problem of what he calls "premature deaths" is, of course, compulsory health insurance.

Just how medical care could prevent accidents from happening, Mr. Ewing does not explain. Nor does he explain what the ambiguous "other" division of 20,000 mortalities includes. Certainly it is a known fact that many infant and maternal deaths result from home environments, the so-called family way of life. Medical practitioners can prescribe proper diets and other requirements for pre-natal care; but the fundamental health needs—adequate housing, good food, proper clothing—fall outside medical jurisdiction. Furthermore, personality and character traits must be taken into consideration in any study of maternal and child mortality and morbidity rates. Expectant mothers may not have a "will to health." This will to health is reflected elsewhere in the studies of general population groups; for it is to be seen that average expenditures for tobacco, alcoholic beverages and entertainment far exceed the annual outlay for medical care. Families whom Mr. Ewing describes as "medically indigent" may be so only because they have not the will to health; they fail to budget for medical and hospital care. Legislation will not force into a state of healthful living those persons who are not interested in maintaining or restoring their health.

In Mr. Ewing's dream world of 1960 he sees a nation of healthy people; he sees longer life expectancy; he sees research progressing at hitherto unprecedented speeds. The price tag on this Utopia—a 3 per cent tax on all employed or self-employed persons in the United States—he dismisses lightly, for he thinks of this four billion dollars as an investment which will return an estimated 27 billion dollars in one year, this figure representing what Mr. Ewing calls "lost . . . during 1947 in potential production and wages through sickness, partial and total disability."

And how is all this to come about? In Chapter II, Mr. Ewing jousts with the problem of medical manpower shortages and arrives at a three-point answer under the compulsory health insurance plan. Most ominous sounding of the three is his reference to "greater efficiency in diagnosis." Throughout the booklet there is this emphasis on "efficiency"—which leads the reader into a ludicrous visualization of scientists turning out a cancer cure or isolating the polio virus according to a "schedule of operations," or a patient being examined by his physician while a "bureau man" stands by with a stop watch.

And while admitting the shortage of medical practitioners, Mr. Ewing proposes a plan that would burden the already overworked profession

with a mass of bookwork and an ever-increasing case load and which would make further medical recruitment difficult because of the elimination of incentive and the destruction of the idealistic medical code.

If doctors are paid fee-for-service, they must prepare voluminous reports to local, regional or national medical care headquarters, and keep carbon copies of all records in case the doctor must prove in court that he charged the correct amount in a given case, prescribed the *standard* remedies or treatment and treated the patient according to the patient's right under the insurance law.

If doctors are paid stipulated salaries, according to number of patients, location of practice and degree of specialization it must inevitably follow that they will be regimented under a system that will put promotions and salary increases on a political basis, make transfers of practice difficult, perhaps placing the transfers on a promotion-demotion level.

Mr. Ewing scoffs at the logical assumption that there would be a break-down of the doctor-patient relationship under his system. After all, he points out, the patient may choose his physician and the physician may accept or reject patients, or even refrain from participating in the program at all.

This aspect of the problem has been subjected to close scrutiny, both in the light of American medical history and the experiences of physicians in countries which are now and have been under a government medical program similar to the one contemplated by Mr. Ewing. It is agreed, even by Mr. Ewing, that at least the opening years of such a plan would bring a flood of patients queuing their way toward doctors' offices—malingerers and persons with minor ailments, determined to get their "money's worth," would be among them. The patient who now may see the physician of his choice by appointment would, presumably, have to wait if the physician he wished to consult already had a full quota. The same situation might be true of hospital care, for England now under a universal medical care plan has been described as having "hospitals full of patients with ingrown toenails."

If doctors were put on a forty-hour week under this plan, it has been pointed out that the ratio of physician hours to total population would be an average of two hours' time annually for each American. Thus, summary treatment of a large number of patients would be unavoidable; the doctor would simply not have time for a thorough examination and diagnosis of every patient.

The charge has been directed at Mr. Ewing that medicine would become a "political football." He refutes the charge, saying that physicians would maintain their professional freedom. But consider the pressure from taxpayers: with the cost of medical care mounting, as it would, taxpayers would insist that cheaper drugs and medicines be administered. Combinations of drugs probably would be questioned; new and expensive developments by pharmaceutical houses would be regarded with suspicion by the lay public. Research would suffer from the vagaries of governmental appropriations.

Mr. Ewing has sketched a very attractive design for national welfare but as an architect for health he is a failure, for his blueprint requires a material that few physicians would care to use—socialization.

BROOKINGS REPORT SHOWS FLAWS IN HEALTH PLAN

In May, 1947, Senator H. Alexander Smith, chairman of the subcommittee on Health of the Senate Committee on Labor and Public Welfare, asked the Brookings Institution, widely known as a scholarly, unbiased research organization, to investigate and report on the question of compulsory health insurance.

The resultant 267 pages of carefully prepared facts, figures and analyses are heartening indeed to the medical profession, for this documented study concludes that compulsory health insurance is not the way to improve the nation's health.

"It is apparent that the United States under its voluntary system of medical care has made greater progress in the application of medical and sanitary science than any other country," the report states. "This progress is now reflected in low mortality and morbidity rates of infectious diseases and in increased life expectancy. There is every reason to believe that these trends will continue unabated under our present system of medical care."

The authors of the report go on to call attention to the fact that, in many instances, further curtailment of mortality and morbidity rates must await developments in medical science.

They cite the excellent health record already

achieved by the United States, declaring by means of statistics, "Probably no great nation in the world has among its white population better health than prevails in the United States." Amplifying this statement, with regard to the nonwhite population in this country, Mr. Bachman and Mr. Meriam say, "The nonwhites in the United States have materially poorer health than the whites, but the evidence does not indicate that this condition is primarily or even mainly due to inadequacy of medical care."

Proponents of compulsory health insurance seized on the rejection figures of World War II Selective Service boards as evidence that the health of the nation was reaching new lows and, without government intervention, would continue to grow worse. The Brookings report reinforces the position taken by Dr. Maurice H. Friedman *(Reader's Digest)* and the *Nation's Business* in its articles on the matter of Selective Service statistics as a criterion for judging the nation's state of health.

In the first place, these figures were not compiled as a health report. They include rejections for physical reasons, yes, but often these physical reasons were: failure to conform to height and weight standards, loss of fingers, toes, hands and other members, which certainly could not be attributed to lack of medical care. The standards were not in any sense scientific health standards, but were set up to screen out those men who, though perhaps able to carry on normal civilian activities, would not be capable of enduring the extraordinary strains and stresses of warfare. Often, as standards were lowered during the course of the war, rejectees would be recalled for further examination; thus it was that one person could be rejected as many as five times and each rejection would be counted separately in the grand total. Furthermore, the rejection could be for educational limitations or on moral grounds.

Having called the state of the nation's health good and having compared it satisfactorily with other nations of the world, the Brookings experts examine the proposals for compulsory health insurance.

They find it would necessitate a high degree of governmental regulation and control; they look for a topheavy organization of administrators, auditors, examiners, investigators and the like which, added to the increased case loads and the tendency of some practitioners to use the system for their own financial advantage, would cause the cost of the plan to spiral far beyond the rather staggering estimates made by compulsory health plan sponsors.

Although they sift through every phase of the plan, the impartial Brookings researchers are unable to find any advantages in introducing the program.

PUBLIC HEALTH CONFERENCE HAS SECOND ANNUAL MEETING

Health officers, physicians, nurses, health education workers, sanitary engineers and others whose work relates to public health attended the second annual meeting of the Minnesota Public Health Conference, October 8, at the Saint Paul hotel.

Focal point of the day's program was the discussion of proposed legislation which would enable a county or several counties, united, to establish a local health unit, staffed by a health officer, a public health engineer, a supervising nurse, and additional professional and clerical people according to the size and needs of the area served.

The group was divided according to professional interests for the luncheon meetings, with a general session on local health departments in the afternoon. Katharine F. Lenroot, chief of the United States Children's bureau, addressed the banquet session on the subject of maternal and child health care.

FIFTY PER CENT OF INDUSTRIAL WORKERS PROTECTED AGAINST WAGE LOSS

In a study of 1,150,000 establishments, in industries covered by unemployment compensation, the Research Council for Economic Security found that about 50 per cent of the employes enjoy some degree of protection against wage loss during illness. A total of 30,000,000 workers was tallied for the study.

The Council states in its report, "In every state, with or without compulsory legislation, employers realize the need to protect their workers against wage loss during disability, and have extended such protection on a voluntary basis."

Julian F. Du Bois, Secretary

Minneapolis Masseuse Pleads Guilty to Violating Basic Science Law

Re. State of Minnesota vs. Joanne Eugena Swanson

On October 8, 1948, Joanne Eugena Swanson, fifty-six years of age, 1615 Thomas Place North, Minneapolis, entered a plea of guilty in the District Court of Hennepin County, to an information charging her with the crime of practicing healing in violation of the Minnesota Basic Science Law. The defendant was sentenced by the Hon. Paul S. Carroll, Judge of the District Court, to ninety days in the Minneapolis Women's Detention Home. The sentence was stayed for three years, on condition that the defendant refrain, in every manner, from practicing healing illegally.

Mrs. Swanson was arrested on July 14, 1948, by Minneapolis police officers in Room 305 at 608 Nicollet Avenue, Minneapolis, where the defendant was operating a so-called bath and massage parlor without a massage license. Subsequent investigation by the Police Department and representatives of the Minnesota State Board of Medical Examiners disclosed that the defendant was treating patients for arthritis, sinus trouble and other ailments and was charging $25.00 for a series of treatments. The defendant was arraigned in the Minneapolis Municipal Court on July 16, at which time she waived a preliminary hearing and was held to the District Court under cash bail of $1,000, which was furnished. The defendant was arraigned in the District Court on July 19, at which time she entered a plea of not guilty. Her case was set for trial for September 13.

The defendant holds no license to practice any form of healing in the State of Minnesota, but claims to be the possessor of a diploma in massage from a Chicago massage school. The school, however, is not recognized by the Minnesota State Board of Medical Examiners, and therefore, the defendant cannot qualify for a massage license in Minnesota. Mrs. Swanson was so advised in 1943 by the Minnesota State Board of Medical Examiners. Judge Carroll warned the defendant that if she violated the Basic Science Law in any manner in the future, that she would be required to serve her sentence.

Two Minneapolis Women Sentenced for Criminal Abortion

Re. State of Minnesota vs. Claretta Carstenbrock, Blanche Bougetz and George W. Rastede

On October 5, 1948, Claretta Carstenbrock, thirty-nine years of age, residing in rural Hennepin County, was sentenced to a term of one year in the Minneapolis Women's Detention Home by the Hon. Levi M. Hall, Judge of the District Court of Hennepin County. The defendant Carstenbrock had entered a plea of guilty on July 7, 1948, to an information charging her with the crime of abortion. The sentence was stayed and the defendant placed on probation for one year, the Court stating that the only reason the defendant was receiving probation was because she had a good record prior to her arrest in the present case. The defendant Carstenbrock has no medical training whatsoever but had been employed for eighteen years as hostess by a country club.

On the same date, October 5, 1948, Blanche Bougetz, forty years of age, 4544 Lyndale Avenue South, Minneapolis, was sentenced by the Hon. Paul S. Carroll, Judge of the District Court of Hennepin County, to a term of not to exceed eight years in the Women's Reformatory at Shakopee. The defendant Bougetz had entered a plea of guilty on July 21, 1948, to an information charging her with the crime of abortion. Judge Carroll stayed the sentence and placed the defendant on probation for six years. Judge Carroll told the defendant that she was being placed on probation solely because of the condition of her health. Mrs. Bougetz weighs over 400 pounds, and a medical examination prior to sentence being imposed, disclosed that she is in poor health. However, Judge Carroll told Mrs. Bougetz that if she is involved in any more violations of the law, she will be sent to the Women's Reformatory, even if it means that she will die in the institution.

The defendants Carstenbrock and Bougetz were arrested in June, 1948, along with the defendant George W. Rastede, a Hudson osteopath, following an abortion on April 25, 1948, on a twenty-two-year-old LaCrosse woman. The patient was referred to the defendant Bougetz by the defendant Rastede, and the abortion was performed by the defendant Carstenbrock at the home of Mrs. Bougetz. The sum of $300 was paid for the abortion, and the money was equally divided among the three defendants. The defendant Carstenbrock has no prior conviction, but the defendant Bougetz was convicted of abortion in the District Court of Hennepin County on September 6, 1946, at which time she received a suspended sentence of one year in the Minneapolis Women's Detention Home. She also has a previous conviction in 1932 for the crime of forgery in the second degree. For that offense the defendant Bougetz served three and a half years in the Women's Reformatory at Shakopee.

The defendant Rastede entered a plea of guilty on September 21, 1948, to an information charging him with the crime of abortion in the same case as the defendants Carstenbrock and Bougetz. The Court set October 18 as the date for imposition of sentence in Rastede's case. The defendant Rastede also entered a plea of guilty on October 5, 1948, to a second charge of criminal abortion in which he is named with one Michael J. Koehler. The Court set October 18 as the date for sentencing Rastede.

Wisconsin Osteopath Ordered to Surrender License by Minneapolis Judge

Re. State of Minnesota vs. Claretta Carstenbrock, Blanche Bougetz and George W. Rastede.

Re. State of Minnesota vs. Michael J. Koehler and George W. Rastede.

On October 18, 1948, George W. Rastede, fifty-eight years of age, of Hudson, Wisconsin, was sentenced by the Hon. D. E. LaBelle, Judge of the District Court of Hennepin County, to two separate sentences of not to exceed four years each, on two charges of criminal abortion. Rastede, licensed as an osteopath under the laws of Wisconsin, upon recommendation of legal counsel for the Minnesota State Board of Medical Examiners, was given his choice by the Court of serving four years in the State Prison at Stillwater, or surrendering his osteopathic license for cancellation by the Circuit Court of St. Croix County, Wisconsin. Rastede chose to surrender his license for cancellation rather than serve the prison sentence. Judge LaBelle further deprived Rastede of the right to own or operate a hospital or engage in the practice of healing in any manner, directly or indirectly, while he is on probation.

Rastede told the Court that he was born in Dodge County, Nebraska, and that he was a graduate of the Des Moines Still College of Osteopathy. He stated that he had been practicing for the past ten years at Hudson. Rastede admitted that he had been referring pregnant women to his co-defendants, Claretta Carstenbrock,

Blanche Bougetz and Michael J. Koehler for the purpose of having criminal abortions performed. Rastede also admitted that he had shared in the money paid for such abortions. Rastede was arrested in the first case on June 8, 1948, by Inspector Bernath of the Minneapolis Police Department on a warrant charging him with the crime of abortion in connection with a twenty-two-year-old LaCrosse, Wisconsin, girl who was aborted by the defendant, Claretta Carstenbrock, at the home of the defendant, Blanche Bougetz, in Minneapolis. The sum of $300 was paid in that case, the money being split three ways between the defendants, Carstenbrock, Bougetz and Rastede. Rastede was released on $5,000 cash bail in that case, and while out on bail, sent a twenty-two-year-old Chippewa Falls, Wisconsin, girl to the defendant, Michael J. Koehler, for a criminal abortion. Rastede was arrested in that case on August 25, 1948, and his bail increased to $12,500 which was furnished. Subsequently, on September 21, 1948, Rastede entered a plea of guilty to the first charge against him, and on October 5, 1948, entered a plea of guilty to the second charge against him. The cases against the other co-defendants have been disposed of.

The defendant, Rastede, had a previous encounter with the law in Wisconsin, where, on October 14, 1946, a complaint was filed in the County Court at Hudson, charging Rastede with attempting to produce a miscarriage. In that case a twenty-year-old Winona, Minnesota, girl stated that she paid Rastede $100 for an abortion. The patient became ill and was hospitalized at Hastings, Minnesota. On January 9, 1947, Rastede was acquitted of the charge by a jury at Hudson.

Former Chiropractor Sentenced to Jail for Criminal Abortion

Re. State of Minnesota vs. Michael J. Koehler and George W. Rastede

On October 13, 1948, Michael J. Koehler, fifty-one years of age, 1101 W. 28th Street, Minneapolis, was sentenced by the Hon. Earl J. Lyons, Judge of the District Court of Hennepin County, to a term of not to exceed eight years in the State Prison at Stillwater, for the crime of abortion. The Court stayed the sentence and placed the defendant, Koehler, on probation for eight years, provided, however, that the first year of the sentence must be served by Koehler in the Minneapolis Workhouse.

The defendant Koehler was arrested on August 21, 1948, by Minneapolis police officers following an abortion performed by the defendant Koehler on a twenty-two-year-old Chippewa Falls, Wisconsin, nurse. The nurse had been referred to the defendant Koehler by George W. Rastede, an osteopath at Hudson, Wisconsin. Koehler was paid $350 for the abortion. Upon being first arraigned in Court, Koehler entered a plea of not guilty, but subsequently, on September 1, 1948, Koehler withdrew his plea of not guilty and entered a plea of guilty. Koehler has two previous convictions for criminal offenses. On May 24, 1939, Koehler pleaded guilty in the District Court of Hennepin County to an information charging him with having in his possession instruments, articles and medicine for the causing of unlawful abortions. For that offense Koehler paid a fine of $150 and received a one-year suspended workhouse sentence. At that time Koehler held a license to practice chiropractic in the State of Minnesota. Subsequently Koehler was arrested on a charge of criminal abortion resulting in Koehler pleading guilty on July 6, 1944, in the District Court of Hennepin County to an information charging him with that crime. For that offense Koehler was sentenced to one year in the Minneapolis Workhouse. Koehler served 42 days in the Workhouse and then was released because of alleged ill health. Koehler had stated to the Court that it was necessary for him to go to a different climate to safeguard his health. Upon being released it was learned that Koehler had offered to perform another abortion. The matter was called to the attention of the Court and the Court made an order revoking Koehler's release from the Workhouse. Upon being returned to the Workhouse, Koehler was incarcerated until February 17, 1945, at which time he was released to go to California to live with a daughter. Koehler returned to the State of Minnesota in 1947. Koehler's chiropractic license was revoked on September 6, 1944.

At the time Koehler was sentenced by Judge Lyons on October 13, 1948, the defendant Rastede, likewise, had entered a plea of guilty but had not been sentenced.

Adult types of pulmonary tuberculosis have shown an alarming incidence among children of school age in all of the wartorn countries; tuberculosis of bone and joints has increased many times; miliary tuberculosis and tuberculous meningitis in children are now common. In every children's hospital I visited I saw ward after ward of the victims of tuberculosis. In one small country, not atypical of others, I learned that to take care of the known cases of bone tuberculosis alone among children 7,000 new hospital or sanatorium beds were needed. They had only 500 when I was there.—MARTHA M. ELIOT, M.D., Am. J. Pub. Health, January, 1948.

Early Acute Benign Syphilitic Hepatitis With Jaundice

(Continued from Page 1221)

ant symptoms can be eliminated. Bismuth also can produce the above reactions, so it would be well to use a soluble bismuth preparation early in the treatment, because of its more rapid elimination from the body.

Summary

A case of acute early benign syphilitic hepatitis with jaundice is presented. The most satisfactory treatment probably is bismuth combined with penicillin. It seems best to use a soluble bismuth preparation early in the treatment because of its more rapid elimination from the body. Later, if desired, this can be changed to bismuth subsalicylate in oil. If the above method of treatment is employed, a Herxheimer reaction and other troublesome symptoms can be avoided or minimized by daily observation of the icterus index. The modern use of liver biopsy will enable workers to study pathologic changes of the liver in this disease.

Minnesota Academy of Medicine

Meeting of May 12, 1948

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, May 12, 1948. Dinner was served at 7 o'clock, and the meeting was called to order at 8:20 p.m. by the President, Dr. T. A. Peppard.

There were fifty-nine members present.

Minutes of the April meeting were read and approved.

Dr. Ohage read the following memorial to Dr. Alexander Colvin, and a motion was carried that this be published in the Proceedings of the Academy and a copy sent to the widow.

ALEXANDER R. COLVIN
1867-1948

Dr. Alexander R. Colvin was born in Leeswater, Ontario, Canada, February 28, 1867. He received his preliminary education in the Leeswater high school. He then studied pharmacy and, after his graduation, settled in Lethbridge, Alberta, Canada. Here he met a Dr. Newburn who induced him to study medicine. He then entered medical school at McGill University at Montreal, Canada, from where he was graduated in 1894. Following his graduation, he spent two years in the Royal Victoria Hospital as an intern and surgical resident.

Upon completion of his residency, he came to La Crosse, Wisconsin, to take over the practice of Dr. Evans while the latter was studying abroad. It was at this time he decided to locate in Saint Paul. The same year, on June 1, 1897, he was married to Miss Sara Tarleton.

In 1902, Dr. Colvin, accompanied by his wife, went to study in Germany and Austria. He received his postgraduate work at Breslau, Germany, where he studied under the famous Mikulicz, and also in Vienna.

He returned to Saint Paul and became associated with Dr. Charles Wheaton and later with Dr. John Rogers and Dr. Warren A. Dennis, with whom he practiced for many years. He retired in 1948, after fifty-two years of continuous practice.

Dr. Colvin was commissioned a major in the medical corps during the first World War, the highest rank in the medical reserve corps at that time.

Following the war, in 1919, Dr. Colvin was named chief of the surgical staff of the Ancker Hospital, a position he held until the time of his death. He was also a clinical professor of surgery at the University of Minnesota.

He owned and operated the first x-ray machine in Saint Paul.

On January 19, 1948, Dr. Colvin was honored by the members of the surgical staff of the Ancker Hospital and other friends of the profession at a banquet held at the Minnesota Club. This was the last occasion on which Dr. Colvin had an opportunity to meet his many friends and admirers.

Dr. Colvin was a member of the American Academy of Orthopedic Surgeons, the Minnesota Academy of Medicine, American Medical Association, Western Surgical Association, American College of Surgeons, Saint Paul Surgical Society, Ramsey County Medical Society, and The Minnesota State Medical Association, and American Medical Association.

Dr. Colvin was an ardent student of medicine. He was an exhaustive reader and familiar with the English publications on surgery and also the available German surgical literature.

He died on March 22, 1948, at his residence, 1175 Davern Avenue, Saint Paul, Minnesota. He is survived by his wife, Mrs. Sara Colvin, and a niece, Miss Ada I. McKinnon.

A RARE COMPLICATION OF INTESTINAL INTUBATION

OSWALD S. WYATT, M.D.
Minneapolis, Minnesota

Dr. Wyatt's case report was published in the September, 1948, issue of MINNESOTA MEDICINE (page 1022) in the proceedings of the Minneapolis Surgical Society for April 1, 1948.

Discussion

DR. CHARLES E. REA (Saint Paul): The case presented by Dr. Wyatt is very similar to one that was seen at Ancker Hospital about two years ago.

M. L., aged thirteen, was admitted to Ancker Hospital on June 26, 1946. One week before admission she became sick with pain in the abdomen, nausea, vomiting, and fever. On admission to the hospital, she had definite physical findings of a ruptured appendix with generalized peritonitis. A localized mass in the right lower quadrant was drained through a small McBurney incision under local anesthesia on June 27, 1948. Culture of the pus showed Streptococcus viridens and B. proteus. She was treated by means of sulfadiazine, penicillin, streptomycin, blood transfusions, and inhalation oxygen therapy. A Miller-Abbott tube was inserted at the time of admission, and its progress into the ileum followed by roentgenograms. An adequate fluid balance was maintained by intravenous fluids.

From June 27, 1946, until July 3, 1946, she had moderate abdominal distention, and profuse drainage from the incision in the right lower quadrant. At the latter date, Varco feedings were ordered to be given through the Miller-Abbott tube. The student nurse gave the feeding through the "balloon" side of the tube and remarked to the surgical resident that she could not get much of the feeding through the tube. Attempts

to aspirate the solution were unsuccessful. Roentgenograms of the abdomen showed the balloon full of fluid. The tube could not be pulled out. The patient's condition generally became worse. The tube was cut across in the hope that it would pass through the patient, but it did not move. Attempts were made to aspirate and remove the balloon and tube at laparotomies but were unsuccessful due to the patient's poor condition. She died on her thirty-eighth hospital day.

At postmortem there was a generalized purulent peritonitis. The balloon was in the ileum about 2 feet from the ligament of Treitz. It was filled with sour curdled milk. There was no gangrene of the bowel. There was a generalized paralytic ileus.

This complication following the use of a Miller-Abbott tube can be entirely prevented by care in injecting fluids through the right openings. Since the above episode, the surgical resident has been made responsible for the care of the Miller-Abbott tube. On occasion, one can have enough trouble getting the Miller-Abbott tube to work properly without adding a complication.

ADOLESCENT RESENTMENT OF AUTHORITY

EDWARD DYER ANDERSON, M.D.

Minneapolis, Minnesota

It has often been said that adolescence, death and taxes cannot be escaped. This is true, but, under normal conditions, adolescence differs from death and taxes in that it should be welcomed rather than dreaded. Certainly no other period of life can be more full of interest, pleasure and experience. And equally there is no period which can give the parents, the teacher or the physician more interest and satisfaction.

So much has been written and said in recent years regarding the difficulties that can arise in the adolescent period, that many people, including physicians, tend to expect serious trouble and feel that it is bound to be a time of great trial and tribulation for all concerned. Although it is true, even in the normal youngster, that there are occasions which are disturbing and troublesome, usually these are episodes which are not lasting nor serious. During normal infancy and childhood occasions arise which are not pleasant for either the child or the parents, but they do not make us forget the wonderful, pleasant and interesting parts of these periods of growth. The same applies to adolescence, which is also a period of physical and emotional development. Regardless of the occasional disturbing episodes which occur, it is usually a normal, pleasant and interesting part of life. It is extremely important that we physicians do everything in our power to help young people, parents, teachers, social workers, nurses and everyone dealing with this age group to recognize and understand the normalcy of adolescence. We can best do this by helping all concerned to have an understanding of the normal physical and emotional changes that take place.

This paper is written with the hope that it may be of some help in better understanding and interpreting adolescent resentment of authority which is so often confusing and disturbing to adolescents and their parents. Unless understood, it can cause a tremendous amount of misunderstanding, friction and unhappiness. On the other hand, if the subject is wisely handled by parents and others in authority, the normal adolescent will have no serious or permanent difficulty.

This increasing and, at times, overwhelming resentment of authority, even though normal, is sometimes called adolescent revolt. I believe this latter term should be confined to those instances in which the adolescent has gotten completely out of hand for one reason or another and has revolted. One can expect fairly frequent evidences of resentment of authority in the youngster who is emotionally healthy, but not actual revolt. If the emotional growth and development of the youngster has been normal before adolescence and if the parents are understanding and wise during this critical period, abnormal resentment and revolt will not occur.

Adolescent resentment of authority differs from the normal dislike all of us have of being directed or crossed in our desires by someone who has authority and control over us. This adolescent resentment is beyond that which one would normally expect, and often occurs when perfectly reasonable requests are made. There is no logical reason for some of the extreme feelings of resentment and hostility which occur when the parents direct, mildly criticize, or disagree with the ideas of their adolescent child. Another characteristic which is confusing to both the child and the parents is the fact that what may cause no resentment one time may cause an extreme disturbance at another.

There are probably several reasons for this increasing and apparently unreasonable resentment of authority during adolescence. It is believed by some that it is an inherent phase of growth and development which is part of our heritage. Another factor in bringing about this resentment is that when they reach this age they have matured enough to recognize that those in authority, and this applies particularly to their parents, are not perfect and they are disillusioned. Up until this time they have tended to accept without question that the parents were always wise and completely competent to direct all situations. They now realize they do have faults and imperfections and resent the fact that they have been wrong in their judgment. Also because of the confusion, anxiety and uncertainty that often develops because of the marked physical and physiological changes taking place, the adolescent may have feelings of resentment which they cannot explain and which become focused upon the parents. We are all prone to blame things which are unpleasant but unexplained, upon those upon whom we are dependent and who usually protect and shield us from such conditions, and the adolescent is no exception. Whatever the reasons for the increased resentment of authority may be, the fact remains that it is an almost universal development and serves a definitely useful purpose under normal conditions. In a persistent, compelling way it calls to the attention of the parents the necessity of their children's breaking away from parental care and management, so they may learn to stand upon their own feet and eventually be able to manage and direct their own lives. If it were not for this increasing desire for independence with resulting resentment of authority, most parents would continue indefinitely to guide, direct

---

Inaugural thesis.

and make all decisions for their children. The result would be that when the young man or woman reached the chronological and physical age of maturity, he or she would be emotionally immature and inadequate and would flounder helplessly when put upon his or her own resources. We see frequent examples of this in adults who were overprotected and never allowed to mature and become independent, with resulting inability to be happy or successful in their marital, social or business life. Adolescent resentment of authority is one of the principal reasons that there are not more such tragedies.

The symptoms of normal adolescent resentment of authority differ with different individuals, but usually the first of these to appear is a strong, unexplainable feeling of resentment toward the parents when an apparently reasonable request is made. Things which they have previously done and accepted without any question or resentment, are obeyed, but with bad grace and an air of grievance. These feelings of resentment and the resulting flare-ups tend to become more and more frequent and intense and, before long, the adolescent begins to speak his mind and register firm objections to advice from or direction by the parents. It should be noted that in most youngsters this resentment is almost entirely directed towards the mother and father, and not to others in authority. Although there may be considerable talk against the authority of the teacher, the principal or the coach, in most instances the adolescent actually feels or shows little resentment towards them. Because parents largely represent authority to the adolescent, they bear the brunt of this growing resentment. This shows itself in many other indirect ways. The adolescent often begins to be ashamed of how his father and mother dress and look. He may become ashamed of their manners and friends, and frequently of his father's jokes, and will cringe both inwardly and outwardly when one is told in the presence of his own friends. All of this regardless of the fact that the parents do dress in perfect taste, have excellent manners and wonderful friends and even the father is a superb storyteller. During this period the adolescent boy or girl begins to disagree with the religious, ethical and political ideas of his or her parents. It is useless to discuss their ideas with them, as they are unable to enter into a discussion except upon an emotional plane and they become markedly upset if one does not agree with their viewpoint. All of this might sound as if adolescent resentment of authority leads to a pretty grim and unhappy time for both the parents and the youngster. Under normal circumstances, this is not so. In the first place, these periods of resentment are usually of short duration. Secondly, if the adolescent is wisely handed, as he gets nearer and nearer to adulthood, he more and more realizes that his parents are not complete social and intellectual failures, and actually begins to like and respect them. As a matter of fact, the normal adolescent feels this way towards his parents most of the time and it is only occasionally that he is disturbed and resentful. Although all the symptoms mentioned may occur on occasion, the relationship between the normal adolescent and his parents is a happy, friendly and relaxed one most of the time.

Although most adolescents have no serious trouble with resentment of authority, unfortunately there are some who do. Although this paper is primarily upon normal resentment of authority, I do wish to discuss briefly adolescent revolt which is sometimes seen. The abnormal symptoms may be varied, but the most common is open defiance toward the parents. This may take the form of defiant, belligerent or even profane speech. There may be complete disobedience and in extreme cases the disturbed youngster may physically attack the parents when crossed, corrected or denied what he wants. The parents may lose all control, and a state of anarchy results. A boy or girl in a state of revolt is usually restless, sullen and unhappy a great deal of the time. A frequent symptom of abnormal revolt is the projection of feelings of hostility and defiance beyond the parents to the authority of the school and even the law. The youngster begins to be a disturbing element in school, with refusal to do the required work, defiance of the teachers, truancy and general trouble-making. When the resentment extends to the authority of the law, the adolescent may become delinquent.

It should be noted at this time that many normal adolescents go through a varying period during which their school work suffers. Most of these youngsters do not know why their work slumps and are mildly disturbed about it and welcome help in the matter. In most instances it is the result of the general mild disturbance and confusion brought about by the increased need for recognition and acceptance, and the new problems and conflicts resulting from the increased sex urge and interest. Also, the interests of the adolescent suddenly widen and increase, and school work may temporarily suffer.

The adolescent who fails in school because of abnormal revolt, differs from the normal youngster who has scholastic difficulties at this time by taking a belligerent attitude about the whole affair. He tends to glory in his failures, blame his teachers for his difficulties and more or less defies the parents and school to help him or do anything about it. Also, his poor work in school tends to continue indefinitely, while that of the normal adolescent is usually of comparatively short duration.

Frequently the adolescent who has abnormal feelings of resentment and revolt finds it difficult to get along with his friends and contemporaries. He has numerous arguments and disagreements and often seeks new friends among those who are also disgruntled, unhappy and emotionally disturbed.

There are some adolescents who react abnormally to feelings of resentment of authority by becoming shy and withdrawn. They never assert themselves or argue when corrected or denied what they want. They show no outward evidence of resentment and seem perfectly willing to be completely dependent upon and dominated by their parents. They tend to stay by themselves, to have few friends, and parents, teachers and schoolmates find it extremely difficult, if not impossible, to establish any close relationship with them. They are

very unhappy and are seriously emotionally ill youngsters. They and their parents are badly in need of help.

There are many causes for the development of abnormal and unhealthy reactions to adolescent resentment of authority. We can assume that an adolescent showing abnormal signs of resentment and revolt was either extremely unstable and disturbed when he reached this age, or the parents were unwise in their management during this period, or both. In most instances, both factors are involved, as parents who manage their children improperly and unwisely before adolescence, with resulting emotional insecurity and instability, usually continue to do so when this age is reached. It is certainly true that a child who is emotionally disturbed or ill when he reaches the adolescent age is almost bound to have an overaccentuation of all normal adolescent problems and this is particularly true of resentment of authority. Such children almost invariably show symptoms of abnormal resentment and revolt. There are obviously many conditions and factors that can cause the fundamental emotional disturbance.

The child who has been overprotected and spoiled is almost sure to have trouble. This is also true of children whose parents are too perfectionistic, demanding or strict.

If one or both parents have consciously or unconsciously rejected their child, a real storm is almost bound to occur when adolescent resentment of authority develops. We know that children unconsciously recognize the fact that they are rejected, and it accentuates their resentment of the authority of the parents. Here we have a personal resentment added to that directed against authority itself.

If one or both parents are delinquent, the adolescent often has difficulty with revolt because of feelings of resentment, shame, lack of respect and motivation. Adolescents who have grown up in a home where there is unhappiness and friction between the parents or which has been broken because of divorce, are particularly prone to develop trouble with resentment of authority. This may also be true when a stepfather or stepmother comes into a family which was previously broken because of death or divorce.

Adolescents who have been frustrated and thwarted during childhood because of a physical or mental handicap frequently have serious difficulty in properly handling resentment of authority. Many mentally handicapped adolescent delinquents come under this category.

There are numerous other causes for emotional insecurity and instability which time will not allow us to enumerate or discuss. However, I wish to emphasize again that whatever the cause, a youngster who is emotionally disturbed when he reaches adolescence is very likely to have difficulty with otherwise normal changes which come at this age. This is particularly true of adolescent resentment of authority. Unwise management of this resentment can lead to disaster in the emotionally stable and healthy youngster, and it is sure to do so in those who are emotionally ill. In cases where the disturbance is severe and of long standing, special psychiatric diagnosis and treatment may be necessary. However, these cases are the exception. The great bulk of preventive mental hygiene and treatment which is so greatly needed can best be done by physicians coming in contact with the adolescent and his parents in the course of regular practice. The understanding and relationship between the majority of parents and their adolescent children is excellent and, in most instances, all that is required is for the physician to give information, support and encouragement. Other adolescents and their parents may need a great deal of instruction and advice regarding the normal reactions and developments of this age so they may understand and meet situations as they arise. Some adolescents present symptoms which indicate abnormal reactions, and physicians can often prevent serious and permanent damage by early recognition of danger signals and the giving of proper counsel and help to correct the underlying cause.

If a few general principles are followed in handling the adolescent and his feelings of resentment toward those in authority, many difficulties that may otherwise develop will be prevented and some of the more seriously disturbed youngsters may be helped.

First, parents should not consider or take the resentment and consequent behavior of the adolescent as a personal affront. This is one of the most frequent mistakes made, as parents often do not realize that their youngster is resenting authority itself and not themselves as individuals. The parents represent authority and therefore will have to bear the brunt of the resentment. They should remember that if someone else had been the parents of their adolescent children they also would have been the object of this same resentment. It is hard not to become hurt and angry when children say and do things which seem so unreasonable, ungrateful and unjust; but if parents can avoid taking it personally, they will save themselves and their children a great deal of unhappiness and heartache. By attempting to treat the whole situation impersonally, the relationship will be kept from becoming a personal fight. Both parents and the child too frequently lose all sense of proportion and say and do things which certainly do not help the situation.

Secondly, parents must keep their sense of humor. Many of the things the adolescent does and says are funny. It may be hard to appreciate the humor at the time, but if parents do not take things too seriously, many a tense situation can be relieved and things will go more smoothly. Obviously, a sense of humor cannot prevent or solve all problems of adolescence, including that of resentment of authority, but it certainly can help a lot.

Thirdly, parents should learn to avoid unnecessary issues between themselves and their adolescent child, and learn to *meet those which are necessary.* This is one of the hardest things for parents to learn. They tend to make one of two mistakes, or both. They either are too rigid and severe, or, because of dislike and fear of an argument or an unpleasant scene, are too lenient and allow their youngsters to do and say things which they should not. Some parents do what is even worse, namely, go from one extreme to the other, with resulting confusion and bewilderment to the child. Another mistake is frequently made when the adolescent begins

to indicate his desire to be independent and shows resentment of authority. The parents either become resentful and angry, or become panicky and fearful that their child is showing evidences of incorrigibility and delinquency. In either case, they fail to recognize the normalcy of this resentment and become more punishing, nagging, and restricting in their attitude, instead of allowing more liberty, responsibility and freedom. This causes the adolescent to become more and more resentful and he then tends to revolt against what he considers unjust treatment. The parents in turn become more strict and a vicious circle is established. Unless the parents can be helped to break the circle, the adolescent's resentment can become so great and uncontrollable that real revolt develops. Unless it is broken, there is also the danger that this resentment will not only be directed against the parents, but may project out to include resentment against the authority of the school and, in extreme cases, to that of the law, with resulting behavior problems and failure in school or actual delinquency. Also, as pointed out before, in some adolescents, due to inherent sensitiveness and underlying severe emotional disturbance, an even more serious complex may result from this increasing restriction by the parents. The normal and healthy desire to break away and become independent may be crushed, and a withdrawn, shy, unhappy and inadequate person may be the result.

This tendency on the part of parents to increase, rather than decrease, control and restrictions is a common and easy mistake to make. It is hard for most fathers and mothers to realize that the normal adolescent is capable of assuming a great deal of responsibility and of properly making most decisions for himself. Sometimes the decision may not be that which the parents would choose, and at times it may not be the wisest one; but, if the issue is not too important, no real harm has been done, and the youngster has had the satisfaction as well as the experience of making a decision for himself. When adolescents are allowed, insofar as possible, to make decisions for themselves, feelings of resentment which would otherwise develop are avoided. They particularly resent authority which they feel is unnecessary and unjust. It is surprising how frequently they correctly sense the difference between necessary and unnecessary parental interference.

By avoiding unnecessary issues, many feelings of guilt which would otherwise develop can be prevented. When an adolescent develops feelings of resentment toward his parents, he is very likely to think, say or do things which cause both conscious and unconscious guilt. There is not time to discuss in this paper the effect of guilt upon emotional security, but enough has been written and said about it in recent years to make it evident to all that it should be avoided whenever possible.

When parents consciously watch themselves, it is surprising to most of them to see how frequently they make issues of nonessential things and how often they correct, direct or discipline their adolescent children when it is really not necessary to do so. As a matter of fact, the same is true of children of all ages. In most instances, the issue could be avoided and the decision left up to the youngster. Certainly, in most normal adolescents such things as manners, dress, eating habits, companions, constant reporting as to where they are, time to go to bed, number of times to bathe and wash, and many other questions, can be left up to the youngster and it is surprising how well they handle the situation. The average normal adolescent is capable of taking care of most issues and decisions that arise in his daily life, and we physicians must help parents to see the wisdom and necessity of giving their children the opportunity to do so. It should be emphasized again that the decisions may not always coincide with what the parents would like themselves, but the good resulting from the avoidance of nonessential issues far outweighs the effects of an occasional mistake in judgment on important matters.

Important as it is that nonessential issues be avoided, it is equally important that those which are essential shall be met surely and firmly when they arise. It is sometimes difficult to know whether an issue is essential or nonessential, but the proper decision can usually be made if parents are objective in their approach to the question. Although the adolescent can decide adequately for himself in most instances, he is not capable of wisely making all decisions. He knows this himself, though he is usually the last to admit it. The ego of the adolescent is not strong enough to stand without occasional support. If parents do not step in when necessary, and firmly and wisely make a decision, the adolescent will be uncertain, insecure and unhappy. Feelings of guilt, anxiety and uncertainty will develop unless he knows that his parents will keep him from doing things which he himself recognizes as wrong, but which he may do if not prevented. There are times when parents must take a definite and firm stand regardless of whether the youngster can understand it or not and regardless of whether he will feel unhappy and insecure or not. To neglect to do so might be the cause of the adolescent getting into serious trouble. It is the responsibility of the parents to step in at these times and make the decision without question or argument. It should be made immediately and with absolute finality. Although the youngster should know the reasons for the decision, there should be no argument or wrangling about it.

When it becomes necessary for parents to take a stand contrary to the adolescent child's wishes, care should be taken to differentiate between the act itself and the motive behind it. What the youngster wants to do may be inadvisable, and the parents may have to refuse to let him do it. However, it may be perfectly normal and understandable that the adolescent wishes to do it, and one must not condemn him for wanting to do the particular thing that has to be forbidden. This is an easy mistake to make, but a dangerous one, as the boy or girl is bound to be extremely resentful of an unfair judgment of their motives. On the other hand, if they know their parents are understanding, they will accept a refusal of something they wish to do with much less resentment than when their motives are unjustly criticized. An example of this would be the case of an adolescent who wishes to stay out until three or four o'clock after a party. Because of health, age, or other reasons, the parents may have to refuse to

allow him to do this, but it is certainly not abnormal or wrong for the child to wish to do so. In fact, it would probably be abnormal if he did not want to. If criticized for wanting to stay out, as well as being denied the right to do so, resentment will be greater and more lasting than if he feels his parents understood his wish, even though they could not allow it.

To summarize this important question of discipline with the adolescent, avoid all nonessential issues and allow them to have as much freedom, liberty, and responsibility as possible. However, when it is necessary to take a stand upon an important issue, do so fairly, justly, and understandingly, but immediately and definitely. If parents of adolescent children who are emotionally normal and healthy will consistently handle discipline in this way, they will find that neither they nor their children will have much real difficulty with resentment of authority.

In conclusion, I wish to emphasize again the normalcy of most adolescent reactions and changes. Because of lack of knowledge and understanding of the subject, a great deal of unnecessary unhappiness and even permanent emotional trauma develop. Although there is an unusual opportunity to do constructive mental hygiene work in this age group, it has often been neglected in the past. There is a tremendous need by adolescents and their parents for the counsel, help and advice of physicians. Physicians working with adolescents will find them most appreciative, interesting and lovable, and the rewards are very great both in terms of help given, and in personal pleasure and satisfaction.

Discussion

Dr. E. M. Hammes, Saint Paul: I enjoyed Dr. Anderson's paper very much. It reminded me of what Dr. Lawson Lowrey, who established the Child Guidance Clinics in this Northwest once said—"It is wonderful how well our children develop considering the handicap we parents are." Dr. Anderson's excellent presentation is a definite challenge to both parents and medical men. The adolescent period is the most difficult period in the developing child. Fortunate indeed is the youngster whose parents can overlook the many and trivial annoyances that occur daily, and at the same time can lend a guiding hand to assist in the more serious problems, very vital in the proper emotional and moral development of this adolescent period.

Dr. C. N. Hensel, Saint Paul: Perhaps, if we had more physicians with Dr. Anderson's perception in dealing with the emotional problems of the adolescent boy and girl, we might not find so many maladjusted adults in our offices.

As I listened to Dr. Anderson's thesis, I thought to myself how lopsided is our bringing up; our parents seem to feel that if they give us a religious education and our school teachers give us proper schooling, that that is all the preparation we need in facing the problems of life.

Yet last fall, at one of our meetings, we listened to Dr. Beek's thesis on "Educational Class Therapy" in handling maladjusted adults. Quite obviously maladjusted children grow up into maladjusted adults.

Now we hear from Dr. Anderson that he is working on maladjustments in their incipiency. It seems to me that this is a tremendous field, and apparently Dr. Anderson is the first one in this community to recognize this need. He has taken compassion on the bewildered child and his equally bewildered parents and tried to help them, and now he comes to this meeting and tries to help the bewildered doctor.

I think this is a splendid presentation and very important.

Dr. F. W. Lynch, Saint Paul: Dr. Anderson deliberately avoided consideration of the physical changes which occur in adolescence, but I hope he will not mind discussion of one of these features. One might question the propriety of a dermatologist's discussing this presentation, but I believe that we see more adolescent patients than do specialists in any field other than pediatrics. Acne is extremely common, perhaps occurring in more than 90 per cent of all individuals at some time during adolesence. This is the disease which brings most adolescents to our offices. Since the condition is so common, it is difficult to evaluate the emotional factors related with its occurrence. However, when one examines patients whose acne has persisted into adult life or has developed in later years, then one can usually find evidence of both endocrine and emotional factors. It seems to me that the endocrine factors may be secondary rather than primary, and I wonder just how important the emotional factors may be in causing these eruptions, not only in the older persons but also in the adolescent individual. Some of the emotional response may be related to the parents' tendency to overemphasize hygiene and diet in these cases. Often these patients are led into the office by a dominant parent who insists on giving the history, asking and answering the questions, and taking the responsibility for treatment, leaving the adolescent individual completely helpless while in the office. Many others come in alone, without too great concern about their eruption, but forced to come because the mother or father has insisted that the adolescent take the initiative and assume responsibilities which he is not yet prepared for. These two groups will include the vast majority of the adolescents whom we see with acne.

Dr. Anderson has pointed out that the adolescent individual often responds to parental demonstrations of authority by resentment, or even revolt, and another group respond by withdrawal and the development of shyness. It is my impression that the patients with acne tend much more to fall into the latter group. It seems to me that acne is often associated with very serious emotional disturbances, and I wonder whether they may not be contributory in many instances rather than occurring as a result of the appearance of the eruption. I wish that Dr. Anderson would express his opinion as to the possible relationship of acne, adolescence and emotional difficulty.

Dr. Anderson, in closing: I wish to thank those who have spoken, for their discussions. I feel, as Dr. Lynch does, that there is a definite relationship between emotional conflict and disturbances and many of the cases of acne and urticaria. My impression is also in accordance with his that acne, by and large, is most frequently seen in the withdrawn group of children. However, one must raise the question as to whether the withdrawal is the cause or the result of the acne.

Before closing, I wish again to emphasize that adolescence should be and usually is a period of normalcy, interest and pleasure. In our dealings with young people of this age and their parents, we should endeavor to help them through by our approach and understanding of the changes and problems that arise so that they can meet them wisely. By so doing, a great deal of difficulty, unhappiness, and actual tragedy can be prevented.

The meeting was adjourned.

Minneapolis Surgical Society

Meeting of May 6, 1948

L. Haynes Fowler, M.D., Presiding

FIBROUS STERNOMASTOID "TUMORS" OF INFANCY

Their Role in the Etiology of Muscular Torticollis

LAWRENCE M. LARSON, M.D., Ph.D. (Surg.), and JOHN H. ROSENOW, M.D., M.S. (Surg.)

Minneapolis, Minnesota

Congenital muscular torticollis is an abnormality occurring in the newborn, the main characteristic of which consists of a tumor which involves one of the sternomastoid muscles and produces a torticollis. The salient feature for which the surgeon is called is the mass in the neck which closely resembles and often is confused with a malignant tumor. We wish to emphasize that this type of torticollis is not to be confused with the numerous other types of traumatic, infectious, neoplastic, structural or paralytic diseases, conditions which lie in the domain of the orthopedist. This condition is one of scar transformation and contraction of the sternomastoid muscle, which, if corrected surgically at an early stage in the disease, before the development of skeletal and permanent deformities, will result in a high percentage of cures. This is possible without the use of long-continued splinting, casts, or stretching maneuvers, and consequently is of importance to general surgeons who are likely to be called first to see these cases. This fact should be emphasized since it has been estimated that approximately two-thirds of all cases of fully developed torticollis result from this pathologic entity in childhood. The gross resemblance of the disease to neoplastic changes in the sternomastoid muscle is often striking and has occasionally been an additional source of confusion. In large medical centers, of course, this problem is encountered with moderate frequency by pediatric surgeons, but its relative rarity in the experience of the general surgeon seems to make this presentation worth while.

Torticollis, or "wryneck" may be the result of one or more of a host of different factors, as seen in Table I.

The type with which this discussion is concerned is the last and is of purely congenital origin. It is quite rare, occurring about once in every 150,000 births (Howell), and is only one-tenth as common as club foot. There is no racial predisposition, and it is seen in equal numbers in males and females. In a review of the literature by Hough it was found that 45 per cent are on the left side and 55 per cent on the right.

This condition rarely manifests itself at birth, but usually about the tenth to the fourteenth day there appears a hard fusiform swelling in one of the sternomastoid muscles which may reach the size of an olive.

TABLE I. CLASSIFICATION OF TORTICOLLIS

1. *Structural*
   - (a) Osseous
     - Hemivertebrae
     - Congenital fusion of cervical vertebrae
     - Klippel-Feil syndrome
     - Malformation of skull and vertebral processes
     - Cervical rib
     - Pterygium colli
     - Compensatory to structural defects of dorsal and lumbar spine
     - Spina bifida
     - Postrachitic
     - Sprengel's deformity
   - (b) Myogenic
     - Congenital absence of cervical muscles
     - Congenital hypertrophy
2. *Paralytic*
   - Erb's
   - Spasmodic
   - Anterior poliomyelitis
   - Spastic paralysis
   - Postinfectious (neuritis)
   - Post-traumatic
3. *Vascular*
   - Congenital
   - Anterior scalenus syndrome
4. *Infections*
   - Retrotonsillar abscess
   - Otitis media
   - Myositis
   - Cervical abscess
   - Spondylitis
   - Meningitis
   - Cervical adenitis
   - Retropharyngeal abscess
   - Mastoiditis
   - Infections of cervical vertebrae
   - Arthritis and synovitis
   - Cutaneous infection
   - Fascitis
   - Infections of congenital cysts and diverticula
   - Spontaneous dislocation of cervical vertebrae
5. *Traumatic*
   - Fractures and dislocations of cervical spine
   - Fractures of cranial base
   - Trauma of cervical fascia, muscles, nerves, et cetera
   - Fracture of clavicle and scapula
6. *Functional*
   - Hysterical
   - (?) Spasmodic torticollis
7. *Ocular*
   - Visual defects, corneal scars, et cetera
   - Muscular
8. *Aural*
   - Deafness
   - Vestibular
9. *Scar formation*
   - Burns
   - Trauma
   - Lupus, et cetera
10. *Neoplastic*
    - Local: Osseous, Myogenic, Lymphatic
    - Central: Vascular, Nerve
11. *Congenital*
    - Posture in utero
    - Trauma at birth
    - (?) Ischemia of muscle

Torticollis is present. The muscle feels short, fibrous and inelastic, and the head is tilted toward the affected side and the face toward the opposite. If not treated, the "tumor" gradually disappears, but the muscle remains as a fibrous cord. With growth of the neck, the torticollis increases because the sternomastoid does not lengthen. As a result of this imbalanced pull, a facial asymmetry develops, the level of the eyes changes, the clavicle and shoulder become elevated, the skull becomes foreshortened in the fronto-occipital diameter (called by some "facial scoliosis"), and the mastoid process becomes more prominent. The condition then becomes a far more serious problem and is of major orthopedic importance. This discussion does not include this type of case.

Etiology

A review of the literature indicates that there are many theories of etiology, without any general agreement, although of recent years certain theories have generally been discarded, among which may be mentioned the hereditary, neurogenic and infectious theories. For detailed discussions, reference should be made to the articles of Chandler and Altenberg, Fitz Simmons, Fisher, and Hough.

A theory which gained much support in the past was that the condition arises as a result of an actual tear in the muscle during birth, followed by a hematoma which becomes organized. More recent authors give little credence to this, because of some of the following considerations. Although it is true that a majority of these infants are born following difficult or breech deliveries, still many with the typical sternomastoid condition are born following perfectly normal deliveries. Also, the "tumor" is never noted immediately following birth, and when found at the usual ten to fourteen day interval it is always hard and fibrous, never soft or fluctuant. In addition, hemosiderin or actual hemorrhage is never seen microscopically.

The theory of occlusion of the arterial blood supply of the muscle during delivery, though popular earlier, is no longer held tenable. As Chandler and Altenberg point out, the pathologic picture in muscle following arterial occlusion is extreme atrophy and disintegration, not fibrosis.

The theory of temporary occlusion of the venous drainage of the muscle has gained much acceptance, largely because of the excellent work of Middleton, and has much to recommend it. Middleton reproduced and amplified the work of Brooks, and applied it to the problem of the etiology of muscular torticollis. He found that experimental occlusion of the venous drainage of certain muscles in dogs would initiate a process of degeneration and fibrosis which would continue even after the venous obstruction was relieved. Most authors in the recent literature accept Middleton's work as pointing to the most plausible etiology.

Chandler and Altenberg, however, felt that Middleton's work was in part fallacious in that his ideas on the blood supply of the sternomastoid muscle, based on the early work of Nove-Josserand and Viannay, were in error. According to these latter authors, the upper, middle, and lower thirds of the muscle have separate vascular supply, and there is little or no cross-communication or anastamoses between these segments. Chandler and Altenberg dissected the sternomastoid muscles of ten stillborn fetuses and felt, on the contrary, that both the arterial and venous systems showed a great deal of overlap and free cross-communications, and that there was, in general, a rich and unsegmented sort of vascular supply. They also pointed out that venous thrombosis can never be demonstrated grossly or microscopically, as would be expected were venous occlusion the predominant factor. They feel that in combination, intra-uterine malposition, trauma at birth, and possibly a pre-existing change of the involved muscle are the etiological factors of importance.

An interesting observation was made by these authors, who found in an antepartum roentgenogram that the fetus was in a breech position, with the head in right lateral flexion. The infant was delivered by Cesarean section and had a torticollis, in which, fourteen days later, the usual "tumor" developed. From this case they emphasize the point that intra-uterine torticollis could prevent engagement of the fetal head and thereby cause a breech presentation. The inference follows that in all cases of breech delivery the obstetrician and pediatrician should make a thorough inspection to detect this abnormality.

From the foregoing it seems that no one theory explains the condition and that several etiologic factors may operate to produce this deformity, such as malposition within the uterus, trauma during delivery, and local ischemia. These may each act in various degrees to cause this pathologic entity by rendering this muscle atrophic, maldeveloped, fibrosed and ultimately shortened.

Pathology

Grossly, the "tumor" is usually not a discrete one but a fusiform swelling of a goodly portion of the entire muscle, at times involving its entire length, hard in consistence, and, on cross section, white, fibrous and glistening. Microscopically the muscle cells are almost entirely replaced by dense, fibrous, collagenous connective tissue. What few muscle fibers remain are seen to be in varying stages of degeneration, with swelling and vacuolization, some with many nuclei. There is an absence of muscle striations, and changes in their staining characteristics are present. No evidence of hemorrhage nor any hemosiderin is found. In the later stages more and more of the muscle tissue disappears, and the fibrous tissue becomes increasingly dense and acellular. In the end stage, all that remains is dense inelastic hyaline connective tissue with nuclei arranged in parallel rows resembling tendon. This latter picture is that seen in older children, where the muscle is replaced by a firm fibrous cord, and is a stage with which, as pointed out earlier, the orthopedist is more concerned than the general surgeon.

Surgical Considerations

It is our feeling that if a definite "tumor" is present in the sternomastoid, it should be removed along with most of the muscle at a very early age, before it undergoes the advanced fibrous change and scar contraction

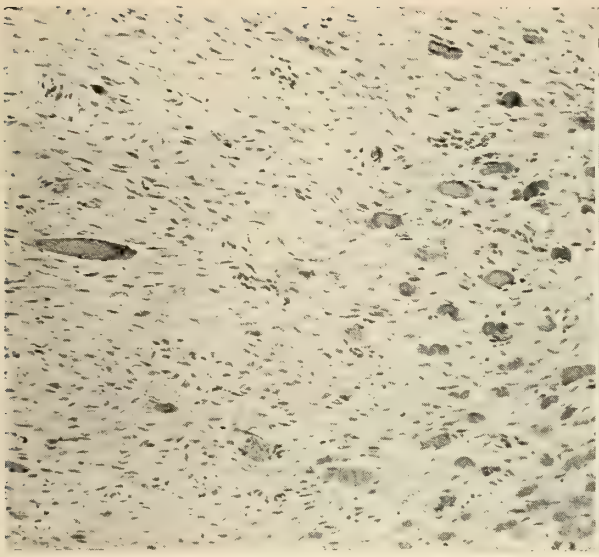

Fig. 1. This slide (magnification 65x) shows an area where muscle merges into the dense fibrous tissue. Numerous isolated degenerating bits of muscle tissue can be seen.

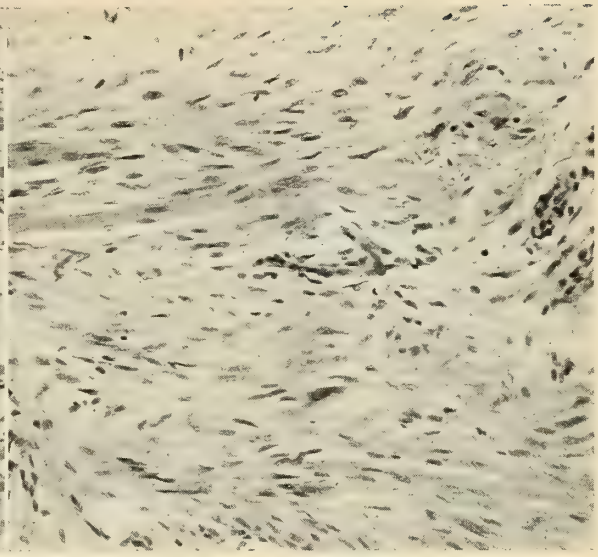

Fig. 2. This slide shows, at a somewhat higher magnification (200x), the typical picture of the central areas of the mass, namely, dense fibrous tissue. In some places the tissue is quite cellular with relatively young-looking, plump fibroblasts, and in other areas it is more compact with older-appearing collagenous connective tissue.

described. If this is allowed to take place, the child likely will develop an asymmetry of the face, with bony changes and the like, as a result of the increasing and prolonged pull of the contracted muscle. At this stage these patients are around four to five years of age and present orthopedic problems of various types and are not intended to be a part of the present paper.

Technique

In infants of but a few weeks of age, great care and caution must be exercised in removing the tumor mass. A transverse incision about one inch long is made in the lower skin crease just above the clavicle. The platysma muscle is split, and the "tumor" is then separated from adjacent structures on all surfaces by blunt dissection with a small curved forceps. The sternal portion and the clavicular portion of the muscle are isolated. A small forceps is then passed beneath the muscle, and the latter is divided by multiple transverse incisions until freed from the clavicle. The "tumor" is then elevated from the deeper structures of the neck and delivered from the wound. The spinal accessory nerve is isolated and freed by cutting through the tumor so as to spare it. The proximal portion of the "tumor" is cut across transversely at about the junction of the upper and middle third of the muscle. All bleeding points are ligated. The wound is closed by deep sutures and the skin by a subcuticular stitch. A pressure dressing is applied.

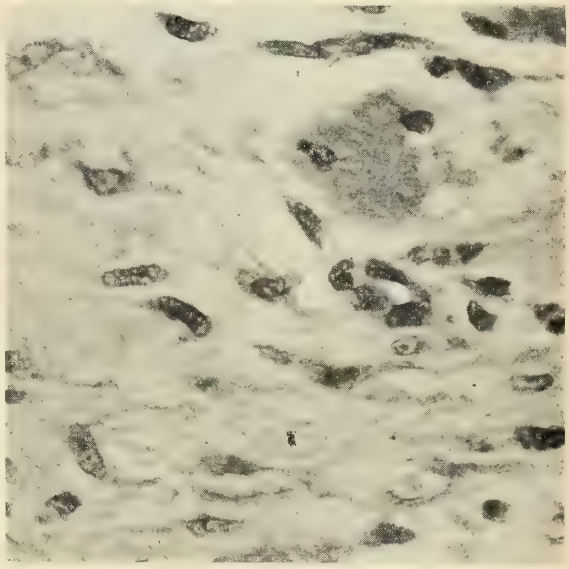

Fig. 3. This slide, taken at a magnification of 800x, well illustrates the intensely cellular character of some of the fibrous tissue, with fat nuclei and delicate collagen fibrils. Also, there is seen a bit of degenerating muscle with loss of striations and vacuolization. It is evident that the distinction between this very cellular fibrous tissue and a very low-grade fibrosarcoma might be difficult. In fact, in one of our cases, the pathologic diagnosis was the subject of a good deal of discussion before the diagnosis of fibrosarcoma was definitely discarded.

Case Reports

Individual case reports of these three infants are so similar as to preclude the necessity of relating them separately. The salient features are hereby all incorporated in the one single description to follow.

Two of the infants were four weeks old, and one was six weeks. All were males. One was born of an entirely normal birth, one of prolonged dystocia, and the third was a breech delivery following twelve hours of difficult labor, and associated with a fracture of the right humerus. All were fairly large infants weighing from 8 pounds 7 ounces to 9 pounds 10 ounces at birth. The right sternomastoid muscle was involved in each case.

The observations of the parents in each case were practically identical. When the child was two to three

weeks old there appeared a noticeable mass in the right side of the neck, associated with distress on the part of the infant when his head was turned to the left. Soon there was a definite tilting of the head to the same side as the tumor, with the chin directed to the opposite side, a position which became a constant one.

Fig. 4. One of the author's patients, two years after operation. Motions of the head and neck are perfectly free. The position of the head is due to the efforts of the photographer to display the area of operation, and not to any structural abnormality. The inconspicuousness of the scar and the lack of cosmetic defect are evident.

Routine general physical examination of all infants, including laboratory work, was negative except for the presence of a cartilaginous, hard, slightly moveable mass in the right sternomastoid muscle. It was best described at the size, shape and consistency of an olive. The head was tilted to the right, with the chin directed to the left, and movements to straighten the head were accompanied by obvious distress.

Using ether anesthesia, a one inch incision was made just above the clavicle near its medial portion, the clavicular and sternal heads of the sternomastoid muscle were detached and the mass then dissected upward. The lower two-thirds to three-fourths of the muscle was then removed, including the tumor mass. The spinal accessory nerve was preserved. Convalescence in each case was uneventful.

The specimens removed measured from 2 by 1 by 1 cm. to 3 by 2 by 1 cm., and all were of the same appearance, being greyish white in color and almost cartilaginous in consistency. On cut section of the tumor, no muscular elements could be seen grossly. On microscopic section the tissue was seen to be a dense collagenous fibrinous connective tissue with rare small bundles of degenerating muscular elements.

Result of Treatment

Follow-up of these cases by various authors ranges from a few weeks to fifteen years, and the results have been most gratifying. The deformity is corrected, and there is full range of motion of the neck. Slight flattening of the neck over the involved muscle is occasionally present but is hardly noticeable, as is also a slight prominence of the clavicle at the sternal junction where the muscle has been severed.

In the author's cases, gratifying results have been noted. The longest time elapsed is now two years, and complete cure is evident in all cases up to date (Fig. 4).

Summary and Conclusion

A firm olive-shaped "tumor" in the sternomastoid muscle of a newborn infant producing torticollis, and appearing ten to fourteen days after delivery, is a fibrous mass and not a hematoma. It frequently resembles a neoplasm in its gross aspects.

The etiology of this condition is not well understood, but one or more of several factors operate in various degrees to produce this pathologic entity. These factors are:

(1) In a uterine malposition with the head laterally flexed and the shoulder elevated, compression of the sternomastoid muscle could take place against the acromion, clavicle and humerus. By this means, interference with development of the muscle could occur, shortening it and predisposing it to birth trauma and to a breech presentation.

(2) Birth trauma due to difficult deliveries, especially those in breech presentation, could account for part of this pathologic picture. With the traction, pressure, and rotation of the neck these infants undergo, it is possible to understand how sufficient trauma to the sternomastoid muscle can occur as to result in its degeneration and fibrosis.

In about two-thirds to three-fourths of these cases there is an associated history of either a difficult or prolonged labor or a breech presentation in the birth of the infant.

The treatment of this condition is resection of the tumor and the remaining fibrous mass representing the sternomastoid muscle. This will correct the torticollis and will prevent later associated deformities of the head and face.

Discussion

Dr. O. S. Wyatt: It is a privilege to be here. I haven't very much to add to the review Dr. Larson has given. It is an interesting anomaly, a congenital anomaly, if you wish, and I think that the etiology of it is particularly interesting. Middleton was an Englishman who did a lot of work on torticollis in 1930, and I am not so sure that his idea of the etiology is perhaps not a pretty

good one. Chandler, too, did a lot of work on torticollis, and I think he stimulated a good deal of interest in it in 1944 when he described the tumor. The type of operation he was doing at that time developed considerable interest throughout the country. Middleton could take the sartorius muscle in the dog and produce an arterial occlusion and still not produce any fibrosis. But, if you cut off the venous supply, a fibrosis will develop. Now, why do we fail to see this in a human being until fourteen days following birth? Middleton proved it impossible. If you prepare the muscle of a dog, you will not find this fibrotic development until fourteen days have gone by; therefore, I am inclined to feel that venous occlusion is probably abnormal in uterine life, and perhaps the condition develops from trauma at birth. I am not inclined to attribute too many etiological factors to the cause of this condition, because it seems to me that there must be a lot of abnormal positions in the uterus.

We don't see this condition very frequently, perhaps once in 1,500 patients, and then most frequently in breech delivery.

One must differentiate sharply, however, when dealing with congenital torticollis. Dr. Larson is not talking about the condition which orthopedists work with when those children are four, five or six years of age, when there is complete fibrosis of the muscle. He is speaking about the congenital tumor which arises in the sternocleidomastoid muscle. When you think you may be feeling glands in the neck, you are feeling this tumor, and it feels like a cartilaginous mass, about the size of an olive. We think that that is the time to remove the tumor, dissecting maybe all the muscle, maybe half and sometimes two-thirds. Those babies wear a collar for a couple of weeks and always get a nice result with good motion, and as they grow up there is no evidence of torticollis when they get to be five or six years of age.

DIAGNOSIS AND TREATMENT OF THROMBOPHLEBITIS WITH SPECIAL REFERENCE TO THE USE OF ANTICOAGULANTS

DAVITT A. FELDER, M.D.
Minneapolis, Minnesota

One often reads articles about the treatment of thrombophlebitis of the lower extremities in which there is no definition of what criteria were used as a basis for including the cases. Doubtless there is a difference of opininon as to whether certain patients actually do or do not have the disease. The value of such articles on this subject might be questioned when many different examiners of varied experience have made the diagnoses upon which the results of treatment have been analyzed.

We thought it would be interesting to evaluate the various diagnostic criteria in our series of patients, at the University of Minnesota Hospitals, who were to be treated with anticoagulants wherever these drugs were not contraindicated.

All of these patients were examined personally and followed by the author, and represent all cases of thrombophlebitis in our hospital from May, 1946, to January, 1948.

From the Department of Surgery, University of Minnesota Medical School, Minneapolis.

Diagnosis

In order to be reasonably sure of the diagnosis of thrombophlebitis, we have included only those cases having at least three of the following signs and symptoms: swelling, vessel tenderness, pain, increased temperature in the limb, dilated superficial veins (unilateral), cyanosis (unilateral), pulmonary embolism (reasonably proven), and change in temperature and pulse (otherwise unexplained). Where unilateral swelling was found alone, or in cases of pulmonary embolism alone without leg signs or symptoms, the cases were followed but not included in this series. In three instances, patients with pulmonary embolism alone developed signs and symptoms of thrombosis in four to five days, and thus were included in the study.

Swelling was the most frequent sign in this series. It occurred in ninety-three (88.5 per cent) of the extremities.

Tenderness was next to swelling in frequency. It occurred in seventy-nine extremities (75 per cent).

Deep calf tenderness, elicited by pressing between the gastrocnemius muscle bellies in the calf, was found to be the most frequent and consistent of deep vessel signs in our series, being present in seventy (66.55 per cent) of the extremities.

Calf-squeeze tenderness is elicited by gently squeezing the calf from side to side. Its value has been stressed by Moses.[11] While probably not as significant as deep calf tenderness, it is an important maneuver in substantiating deep vein involvement when used with the deep calf pressure. It was found in fifty-six (53 per cent) of the extremities.

Homan's sign[6] is the presence of pain in the calf elicited by passive dorsiflexion of the foot. In all of these maneuvers for deep vein tenderness, one must remember to keep the knee flexed, thereby relaxing the calf muscles. This sign was found to be positive in fifty-two (49.5 per cent) of the extremities. Aside from the fact that this sign is the least frequent of the signs mentioned here, we feel it is much less reliable for routine examination because of the great possibility of its being positive with simple muscle involvement alone. It involves mostly muscle stretching and deep vein pressure only secondarily, whereas the calf squeeze and especially the deep calf maneuvers involve more direct pressure over the vessels in question, mainly the posterior tibial and calf veins where most thromboses probably begin.

Popliteal tenderness was sought in all cases and was found in only seventeen instances, and never without other tenderness. This would lead one to believe that it is of limited value as a diagnostic sign.

Anterior tibial tenderness was found in only two instances. Involvement of the anterior tibial veins in thrombosis is not frequent but has been found to be present in a number of instances. This was indicated by fairly definite venographic studies done by the author in patients with chronic deep thrombophlebitis and in a few of the cases in this series. The infrequency of anterior tibial vein involvement might be due to the fact that these vessels do not drain large venous lakes as do the posterior tibials from the calf muscle group.

Frykholm[5] has proposed that collapse of veins with contiguity of vein walls is causative in thrombosis of the deep leg veins in bedridden patients. The anterior tibial vessels are protected from such pressure by their anatomical position.

Produnda femoris involvement, frequently overlooked, has been emphasized by Homans. It is elicited by grasping the biceps femoris muscles and squeezing moderately. In our series none of the twelve cases having profunda femoris tenderness had it as the only sign of tenderness in the extremity. It is quite possible that such thrombosis might conceivably exist alone, but from our observations to date, it would seem to be rare.

We have found that a temperature difference of 3° to 4° F. can be determined fairly consistently by simple palpation. Except for a few instances where an electrothermocouple was used, palpation was used for determining increased temperature, and only definite differences are included.

In fifty-four instances (53 per cent) there was an appreciable temperature increase in the affected limb.

Pain was present in fifty-four patients at rest. Many more had pain in the calf only on walking. A few of the patients described their discomfort on walking as tightness rather than pain. This was noted especially in patients with a high level of thrombosis, as in the iliofemoral thromboses. These patients complained of tightness in the thigh as well as in the calf.

The dusky color often described as a concomitant of thrombophlebitis was noted in only four of our cases.

The presence of dilated superficial veins is sometimes of use in making a diagnosis of deep vein thrombosis. This finding was only noted in three cases in this series. We believe from our experience with patients studied prior to this series and subsequent to it, that this dilatation of the superficial vessels occurs at least twice as often as recorded here.

The sural veins are veins draining the posterior muscle group of the leg. In two cases there was found a simple sural vein thrombosis with surrounding induration of the calf. These thrombi can often be felt on one or both sides of the upper calf just below the knee. This condition should not be treated lightly and is as important as any other deep thrombophlebitis or thrombosis, for such thromboses progress as a rule to involvement of the popliteal vein and from there on up. Many of our cases of deep thrombosis had induration of the calf, probably due to a blocking of the sural veins as they enter the popliteal.

Treatment

It is obvious that the treatment of venous thrombosis of the lower extremities should be directed at (1) the prevention of propagation of an existing clot, (2) the prevention of embolization, and (3) keeping the patient as comfortable as possible both during and after such treatment.

At the beginning of this study it was decided that all patients with thrombophlebitis in the University Hospital would be treated by anticoagulants unless they were particularly unsuited to this form of treatment by virtue of certain contraindications, such as subacute bacterial endocarditis, renal or hepatic disease, bleeding lesions, preoperative to major surgery where in the opinion of the surgeon anticoagulants were not desirable, and in postoperative cases where large bare bleeding surfaces were to be expected.

It was also decided that these patients would be treated with bed rest in moderate Trendelenburg position (the foot of the bed on 4 to 6 inch blocks) as soon as the diagnosis of thrombophlebitis was made. This method of care was prompted by the work of Bauer,[3] who showed fairly conclusively that the rate of venous blood flow was increased by this position, keeping the veins small and free from stasis or laking. The purpose of this procedure is to reduce to a minimum the chances of propagation of thrombi already formed and to discourage new thrombus formation further than might be done by the anticoagulants. It is granted that this procedure colors the total picture. This study was begun when the use of anticoagulants was not as well accepted as it is now, and an added safety factor was thought advisable.

Other points decided on at the beginning of the study were that no patient should receive sympathetic blocks, local or reflex heat or other forms of therapy directed at the thrombophlebitis.

One patient received repeated sympathetic blocks for concomitant or primary peripheral arterial embolism.

Heparin

Since the original work of Murray and MacKenzie[12] and of Crafoord and Jorpes, heparin has come into clinical use increasingly, both as a prophylaxis against primary thrombosis and as a preventive against propagation of the thrombosis already existant.

This drug was used in fifty-four of our cases, exclusively in eight, and with dicumarol in forty-six:

In the first twenty-five cases in which heparin was used, the patients were given this drug intravenously every three hours. An attempt was made to keep the hour-and-a-half clotting time at two to three times the control's or the patient's normal. The majority of this group required 50 mg. of heparin intravenously every three hours to maintain this level of clotting time. A few cases required as much as 60 to 70 mg. for the same effect.

Bauer recommended a dosage of 50 mg. every four hours during the day and 100 mg. at midnight. His series had such obviously good results that we decided to try this method of treatment with heparin, and up to the end of this series of cases had put twenty-five patients on this regimen. In this group, the peak of the clotting time was usually at one and one-half hours and was normal again at four hours.

Clotting times were taken before starting heparin, and then in the early cases every half hour after each dose for two to three doses. It became apparent quite early that the clotting time was down to normal within three to four hours after each injection of 50 mg. and well within eight hours after the 100 mg. midnight dose. This midnight dose of 100 mg. was used merely because we wished to give Bauer's method a fair trial. In only one case in our group was the clotting time

elevated eight hours after the midnight 100 mg. dose.

We tried heparin in Pitkins menstruum in several cases, as recommended by Loewe et al,[9] but could only reproduce his result with twice the dose he recommended. Our experience with this method consists of some dozen patients and is probably too small to draw any just conclusions.

Dicumarol

The action of dicumarol, as described by Link,[8] is primarily on the liver, inhibiting its formation of prothrombin. The anticoagulant effect of dicumarol results only from the diminution in the available prothrombin usually necessary to clot formation. Admittedly it is a potentially dangerous drug when its action depends on the irregularities of intestinal absorption and a special effect on the liver's prothrombin production. For these reasons one must be prepared to follow prothrombin times regularly and to combat the possible results of occasional unpredictable prothrombin depletion that may result before attempting the use of this drug as outlined below.

This anticoagulant was used in seventy-seven of our cases. We gave the average case 300 mg. of dicumarol the first day (100 mg. per 50 pounds of body weight), 200 mg. the second day (two-thirds of the initial dose), and 100 mg. on the third day (one-third the initial dose) providing the prothrombin ratio (control; patient) was not 1.5 or higher. On the second day, dosage was divided into 100 mg. for morning and evening doses. This allowed us to get a little longer spread of our therapeutic level of prothrombin ratio from the initial dosages.

In the early part of our experience with dicumarol we noticed some instances of bleeding from the mucous membranes, wounds, kidneys and so forth. During this time we were keeping our prothrombin ratios between four to five times the normal. As can be expected by the curves of Quick,[13] the prothrombin time shot to extremely high levels, and in some instances the plasma could not be made to clot. In these cases vitamin K, in doses of 72 mg. intravenously, was given, and usually the prothrombin time returned to reasonable levels within ten to twelve hours, and on repeating this dose (if necessary), in another ten to twelve hours the prothrombin time would be normal and stay that way without further dosage. We found also that whole blood transfusions would bring the prothrombin time down, but the longest effect we were able to demonstrate was nine and one-half hours, after which time the prothrombin time gradually returned to a high level. The higher the prothrombin time, the more blood it took to bring the prothrombin time back to normal. Fresh blood was much more potent in this effect than blood twenty-four hours old or older.

In a few cases secondary operative procedures were found necessary after patients had received dicumarol, such as drainage of subphrenic abscesses, et cetera. For these cases, it usually sufficed to give the patient one fresh whole blood transfusion two to three hours prior to operation, so that the prothrombin time was close to normal at the time of the procedure and remained so for eight to nine hours and then rose again. With one patient being treated prophylactically and prepared as outlined above, subphrenic exploration was attended by a good deal of bleeding, and the patient required another transfusion before it was controlled.

After changing our treatment to keeping the prothrombin ratio between two to three times the normal, the incidence of significant bleeding all but disappeared, save for an occasional microscopic or transient gross hematuria.

Duration of Anticoagulant Therapy

The patients with pulmonary embolism were treated the longest. These comprised the group having between fourteen and twenty-one days of dicumarol treatment in therapeutic range.

We attempted to keep our nonembolism patients in range for fourteen days and the embolism patients in range for twenty-one days. The nonembolism patients were ambulated with ace bandage support as soon as all signs and symptoms were negative (usually by the seventh day) and were kept in therapeutic range until treated for fourteen days. The pulmonary embolism cases were kept in bed for at least ten and, in most cases, fourteen days, and kept in therapeutic range until a total of twenty-one days of therapy was reached.

Femoral Vein Ligation

Eight patients in this series had common femoral vein ligations in the presence of one or another of the contraindications mentioned above for the use of anticoagulants.

Pulmonary Embolism

There were twenty-seven patients in this series who had pulmonary embolism. These represent 29 per cent of the entire group. This figure is a little less than the 33 per cent found for untreated cases in a similar group by Welch and Faxon[15] and by Allen.[1] Twenty-one or 78 per cent of these patients already had a pulmonary embolism by the time treatment could be begun.

Six patients developed pulmonary embolism while actually on anticoagulant therapy. These cannot all be considered to have had adequate treatment, however. Four patients had their pulmonary embolism on the first or second day after starting the treatment and so were, in a sense, not adequately treated. These four patients, added to the twenty-one who had pulmonary embolism to begin with, makes twenty-five (92 per cent) of this group who had pulmonary embolism before anticoagulant treatment could become effective.

There were five deaths in our series. In only one of these can we consider pulmonary embolism as the primary cause. All of these patients were seriously ill and, except for one, died gradual deaths from causes other than pulmonary embolism. Three of these patients, however, were found to have pulmonary emboli at autopsy although the emboli were not thought to be the cause of death.

According to the data presented by Welch and Faxon,[15] about 30 per cent of the patients who have one pulmonary embolus from a thrombophlebitis will have

another. They also indicate that out of this group of patients with one embolus, about 25 per cent will have a fatal embolus. In our series there were only two secondary pumonary emboli, and neither of these was fatal.

In nineteen of our patients there were x-ray findings characteristic of pulmonary embolism. Most of the emboli produced x-ray evidence on the right side and showed a preference for the lower lobes. This has been observed and commented on by Roesseler,[14] Allen[2] and others.

A good portion (70 per cent) of the patients had chest pain and hemoptysis. Chest pain was the most common symptom. An occasional patient did not cough bloody sputum for several days, and others had cough without sputum and some neither.

Hemorrhagic Manifestations

Except for a post-transurethral-prostatectomy patient, urinary bleeding was not a source of concern in this group, even though grossly visible in eight cases. In all except two patients no change was made in the treatment and no special measures taken to stop the bleeding. In all of these it cleared up spontaneously within three days.

Peculiar hemorrhagic skin lesions in our patients treated with dicumarol have been observed. These lesions have been accompanied by a burning pain and extreme tenderness. All have healed spontaneously within ten days. No other skin lesions have been noted in our dicumarol-treated patients suggestive of sensitivity or toxicity attributable to dicumarol.

Associated or Primary Conditions

There were nine cases (10 per cent) where deep thrombophlebitis was the primary disease. Careful historical and physical examinations revealed no other significant concomitant disease.

The high incidence of thrombophlebitis in patients with cancer has long been noted[10] and is seen in our study also. In patients with thrombophlebitis one should always suspect and look for a neoplastic process when there seems no apparent causative factor for the thrombosis. In one of our patients it was not until postmortem examination that a carcinoma of the pancreas was found. Cancer was a concomitant or primary disease in thirty-eight of our cases. Forty-one per cent of our patients were treated postoperatively, and, of these, twenty-four had cancer. In all of the patients operated in our hospital during the period of our study, twice as many who had cancer developed thrombophlebitis as those who had no cancer.

Two patients were pregnant when they developed thrombophlebitis of the lower extremities and were given full courses of anticoagulant therapy. Their prothrombin times were back to normal three weeks prior to delivery.

Two other patients developed thrombophlebitis of the lower extremities in the immediate postpartum period and were also treated with anticoagulants under our regimen and recovered without event. We have treated several patients to date with anticoagulants prophylactically in the immediate postpartum period without event. In view of the current controversy in the literature regarding the possible effect of dicumarol on the newborn, none of the mothers were allowed to nurse their babies until their prothrombin time had returned to normal.

During the same period as our study there were sixty hip operations for fracture in our hospital. Four (6.77 per cent) of these developed thrombophlebitis.

A great number of our patients had cardiac disease along with their other difficulties, but no special effort was made to correlate this finding as a separate entity.

As has been noted by Dennis,[4] the incidence of thrombophlebitis in ulcerative colitis is about 30 per cent. In full cognizance of this fact, all ulcerative colitis patients operated in our hospital for ileostomy are given prophylactic anticoagulants. As a result, none of our ulcerative colitis patients having ileostomy operations has developed thrombophlebitis since instituting this prophylaxis.

Summary and Conclusions

The diagnostic signs were evaluated in ninety-two patients (105 extremities) having thrombophlebitis of the lower extremities in an eighteen-month period at the University of Minnesota Hospitals, and it became apparent that the most significant findings were those of swelling, tenderness, temperature changes and pain, in this order.

The most frequently positive and probably the most significant sign of deep vein involvement was deep vein tenderness. Tenderness on calf squeeze was found to be the next most frequent sign and was of appreciable significance in making an early diagnosis of thrombophlebitis.

Color changes, dilatation of superficial vessels and change in vital signs are a definite aid in making the diagnosis, but are of somewhat less significance due to their relative infrequency.

We have presented a method of treatment of deep vein thrombophlebitis with heparin and dicumarol and bed rest in the Trendelenburg position. It is our opinion that this is a rational way of treating most cases of deep vein thrombophlebitis.

The use of anticoagulants in our patients has reduced the incidence of secondary pulmonary embolism from an expected 30 per cent to 2.17 per cent. It has reduced the incidence of secondary fatal embolism from an expected 25 per cent to zero.

Discussion

DR. VERNON SMITH: Thank you very much for the privilege of being here. About a year and a half ago, we started treating patients over forty years of age who had cancer, hysterectomies, hernioplasties, hip fixations, and so forth, prophylactically with dicumarol. We gave them 200 mg. immediately after operation, then approximately 100 mg. daily, depending upon the prothrombin time. We tried to maintain their prothrombin time in the neighborhood of 25 per cent. Even with the prothrombin time above this level we experienced hemorrhage of the pericardial sac on two occasions, hemorrhage from the bladder on one occasion, and hemorrhage from the wound on two occasions. These hemorrhage complications we treated with large doses of Vitamin K, 72 mg. intravenously, and with repeated whole fresh blood transfusions.

A patient who had had a previous embolus after major surgery some four years before was treated with heparin immediately postoperatively after a bilateral hernioplasty. He was given 50 mg. of heparin every four hours intravenously. Three hours after the second dose of heparin, the patient had severe hemorrhages into both of his hernioplasty wounds, and the heparin was stopped at once.

A second patient who had had a previous nonfatal embolus several years before, following a hysterectomy, was treated prophylactically with dicumarol after a cholecystectomy a few months ago. Her prothrombin time was maintained in the neighborhood of 25 per cent. On her seventh postoperative day she developed a sudden severe pain in the right chest posteriorly. Since this was exactly the same postoperative day on which she had developed her previous embolus, and since the patient was quite apprehensive and nervous, we were not certain whether or not this was a pulmonary embolism. There was no x-ray evidence of the same. There was little blood pressure and pulse change. There was no bloody sputum. The patient had been ambulant since the day of surgery. She was treated that night with oxygen and papaverine intravenously but was kept ambulant. The next day the patient's pain disappeared and she had no further interference with her convalescence.

Since we have been following the prophylactic treatment of these patients who are most apt to develop thrombophlebitis or phlebothrombosis, we have seen no pulmonary embolic phenomena of which we are absolutely certain. We have seen no out-and-out thrombophlebitis. There were three patients who might have had a phlebothrombosis involving the deep veins of the calf. Their only symptom was pain on deep muscle palpation and pain on walking. In two of these patients, the pain disappeared after lumbar sympathetic block. The prothrombin times of these patients were maintained around 25 per cent, and they were kept ambulant; no further sequelae developed.

Outside of the occasional case of hemorrhage (3 per cent) that one sees following the prophylactic use of dicumarol or heparin, the only other disadvantages are the expense of the medication (nil with dicumarol), the expense of the laboratory tests, and the pain experienced due to repeated vena punctures.

I believe the time is coming when most of the patients over forty years of age, with carcinoma, hysterectomy, hernioplasty, fractured hip, and so forth, will be treated prophylactically with anticoagulation therapy.

DR. D. A. FELDER: Dr. Smith's experience with the cholecystectomy patient who had the pulmonary embolism is an interesting one. I do not think that dicumarol is the answer to the question of anticoagulants, nor do I think that anticoagulants are the answer to the question of abnormal blood clotting. It is a wonder that we don't get more pulmonary embolism in patients treated prophylactically with dicumarol because, as I mentioned before, dicumarol only cuts down the available prothrombin. Unless the effect is exceptional, such a patient's blood will still clot.

Postoperative ambulation is sometimes merely a description of what may consist of sitting up in a chair for some time on the day of operation and every day thereafter. If anything did predispose to abormal blood clotting, this should. Many patients who have gotten out of bed "early" have been harmed rather than helped. I believe patients must move about for early ambulation to be of benefit. I trust that Doctor Smith's patient was truly ambulatory.

The newer drugs that are coming into use in this field of anticoagulants may help to solve our problem. Heparin is much better than dicumarol, due to its over-all effect on the clotting mechanism. Yet its action is fleeting, and so a prolonged effect is not attainable. There are investigations going on at present with the newer drugs along this line. Dicumarol medication is controlled by the prothrombin time, which is not too satisfactory. After all, prothrombin determinations are indirect measures, and the patient's clotting time might well be different than indicated by the prothrombin determination.

DR. H. O. MCPHEETERS: I would like to compliment Dr. Felder on the fine paper. It was very well prepared and deliberate. What did he say about the percentage of swelling found in his cases?

DR. FELDER: Ninety-three of the cases, or 88.5 per cent.

DR. MCPHEETERS: I am going to take issue with him on the use of lumbar block in the phlebitis case that has a cold, clammy, swollen leg. That type of case will have a fine reaction after a lumbar block. The skin will warm up, and the edema will rapidly disappear.

DR. FELDER: Dr. McPheeters has a much larger and wider experience than I do, and I cannot argue with that experience, but I do know that our patients did well and we did not treat them with sympathetic blocks. Had we done so, their discomfort would have been less probably and we might have changed their course.

DR. C. DENNIS: I would like to say one thing about the simplicity of prophylactic treatment in patients undergoing ileostomy for ulcerative colitis. We don't check the prothrombin time except prior to administration of the drug. With two or three exceptions we have given a single dose of dicumarol. The dose was usually either 200 mgs. or 300 mgs., administered the night before the operation. In twenty cases thus treated, none developed pulmonary embolism or thrombophlebitis. Three patients during this time presented prolonged prothrombin times, and there was enough evidence of liver damage so that dicumarol was not given. All developed one complication after another, and all three died of pulmonary embolism.

AMERICAN ACADEMY OF DERMATOLOGY AND SYPHILOLOGY

The seventh annual meeting of the American Academy of Dermatology and Syphilology will be held in Chicago from Saturday, December 4, through Thursday, December 9, 1948.

The principal sessions will be held at the Palmer House, with special courses in histopathology and mycology scheduled for Saturday and Sunday, December 4 and 5, at the Medical Schools of the University of Illinois and Northwestern University. As in the past two years, teaching clinics will be held on the afternoons of Monday, Tuesday, and Wednesday, December 6, 7, and 8. A new feature is being added to the program this year consisting of informal discussion groups, which will be held at noon and 5:00 P.M. sessions.

Officers of the Academy are: President, Dr. Clyde L. Cummer, Cleveland, Ohio; Vice President, Dr. Francis E. Senear, Chicago, Ill.; and Secretary-Treasurer, Dr. Earl D. Osborne, 471 Delaware Ave., Buffalo, New York.

AMERICAN ACADEMY OF GENERAL PRACTICE

The first annual meeting of the American Academy of General Practice will be held March 7, 8 and 9, 1949, at the Netherlands Plaza Hotel in Cincinnati, Ohio.

The Congress of Delegates will meet at 10 A.M., Sunday, March 6, 1949, preceding the Assembly, and again on Tuesday afternoon, March 8. Scientific papers will be presented on Monday and Tuesday and on Wednesday morning. The presidents and secretaries of the constituent state chapters will meet at dinner on Monday evening, and the banquet will be held on Tuesday evening.

No registration fee will be required of members. Non-members are welcome to attend the sessions and will be charged a registration fee of $5.00.

Members wishing to make reservations may write Chairman, Subcommittee on Hotels, American Academy of General Practice, Dixie Terminal Building, Cincinnati 2, Ohio.

MINNESOTA HEART ASSOCIATION

Members of the Minnesota Heart Association automatically become members of the American Heart Association and receive the monthly publication, "Modern Concepts of Cardiovascular Disease" published by the latter association. Membership dues are annual, $5.00; sustaining, $25.00; contributing, $100; and patron, $1,000. Members of the association are entitled to attend scientific sessions of the association without additional cost.

Physicians willing to display a heart-shaped plastic coin collection device in their reception rooms during the state and national heart fund campaign, February 7-28, 1949, to provide funds for research and education in cardiovascular disease, a fund-raising method approved by the House of Delegates at the last State Medical Association meeting, should communicate with Dr. Paul F. Dwan, president of the Minnesota Heart Association, 2000 Medical Arts Building, Minneapolis 2, Minnesota. Already, scheduled under "sponsorship" of the Heart Association is a two-day continuation course in cardiovascular disease to be held at the University of Minnesota, February 14 and 15, 1949.

ST. LOUIS COUNTY SOCIETY

The first meeting in the 1948-49 season of the St. Louis County Medical Society was held in St. Mary's Hospital, Duluth, on September 9.

Included in the business session of the group was a report by Dr. L. A. Barney, Duluth, chairman of a committee studying county medical fees. During the scientific session, a motion picture, "Problem Child," produced under the authority of the American Academy of Pediatrics, was shown. Dr. R. O. Bergan, Duluth, served as moderator during the showing of the film. In charge of the meeting was Dr. P. S. Rudie, Duluth, president of the organization.

SOUTHWESTERN MINNESOTA SOCIETY

The Southwestern Minnesota Medical Society held its annual series of scientific meetings this fall at Worthington. Evening meetings were held each week from September 13 to November 1 and were addressed by Dr. Lyle Hay, Chief Surgeon, Veterans Hospital, Minneapolis; Dr. Arnold Kremen, University Medical School; Dr. Francis W. Lynch, Saint Paul; Dr. John F. Pohl, Minneapolis; Dr. Lee Forrest Hill, Des Moines, and Dr. T. R. Fritsche, New Ulm.

WABASHA COUNTY SOCIETY

The eightieth annual meeting of the Wabasha County Medical Society was held in Lake City on October 7, with thirty persons, including members' wives and guests, in attendance.

The following officers were elected at a business session of the group: Dr. T. G. Wellman, Lake City, president; Dr. L. M. Ekstrand, Wabasha, vice president,

OBJECT:
DRAINAGE

In discussing the management of chronic cholecystitis without stones, Albrecht states:

"The object of the medical procedure is to assist in draining an infected organ."*

The specific hydrocholeretic action of Decholin (chemically pure dehydrocholic acid) accomplishes this purpose.

Decholin induces bile secretion which is thin and copious, flushing the passages from the liver to the sphincter of Oddi, and carrying away infectious and other accumulated material.

How Supplied: Decholin in 3¾ gr. tablets. Packages of 25, 100, 500 and 1000.

and Dr. W. F. Wilson, Lake City, secretary-treasurer. Dr. E. C. Bayley, Lake City, was elected as delegate to the Minnesota State Medical Association, with Dr. R. A. Glabe, Plainview, as alternate. Named as censor for three years was Dr. B. J. Bouquet, Wabasha, while censors holding over were Dr. T. G. Wellman, Lake City, and Dr. E. W. Ellis, Elgin. It was decided to hold the next annual meeting at Plainview.

The evening program consisted of the following: the President's Address, "Pericarditis," by Dr. R. N. Bowers, Lake City; a talk on "Relations of the Medical Profession to National Defense," by Dr. Jan H. Tillisch, Rochester; and a motion picture entitled "Energy Release from Food," presented by the Upjohn Company.

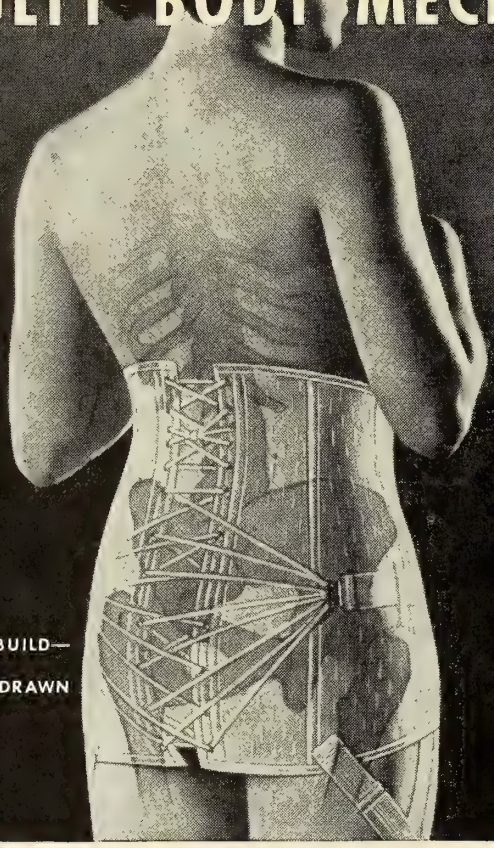
UPPER MISSISSIPPI SOCIETY

The summer meeting of the Upper Mississippi Medical Society, held at Birchmont Lodge, Bemidji, on September 11, was attended by thirty physicians. In charge of the meeting were Dr. D. H. Garlock, Bemidji, president of the society, and Dr. G. I. Badeaux, Brainerd, secretary.

The following papers were presented on the scientific program: "The Physiologic Approach to the Treatment of Nasal Conditions," by Dr. C. L. Oppegaard, Crookston; "Cancer of the Colon," by Dr. Lloyd A. Whitesell, Minneapolis; "Hematic Reactions Following Drug Therapy," by Dr. William A. Coventry, Duluth; and "Acute Conditions of the Gastrointestinal Tract," by Dr. William V. Knoll, Duluth.

WASHINGTON COUNTY SOCIETY

At the Washington County Medical Society meeting, September 14, 1948, a lively discussion took place on the proposal of the Washington County Welfare Board to reduce the fee for doctors' hospital calls on welfare patients from $1.25 to $1.00 per call. This constitutes a reduction from the $1.25 for similar services allowed by the Division of Social Welfare of the State of Minnesota, and both fees are much below the minimum fee schedule of the Washington County Medical Society and other county societies in the state. The society voted unanimously to decline the reduction, and a letter was sent to the Washington County Welfare Board, as a notification of this action, explaining that such fees are out of line with costs for less important services, such as changing a tire or replacing a washer on a faucet.



Dr. William Bernstein of Saint Paul gave an illustrated talk on "Proctological Conditions of Interest to the General Practitioner."

At the meeting held October 12, 1948, the Society voted to accept the proposal of the Red Cross to establish a blood bank in Saint Paul.

Dr. James Edward Jenson, who has recently become associated with Dr. J. W. Stuhr, was elected to membership in the society.

Society members enjoyed an interesting address by Dr. Roger Howell, associate professor of psychiatry at the University of Minnesota on the subject, "Psychosomatic Medicine."

CAMP ANATOMICAL SUPPORT FOR FAULTY BODY MECHANICS

PATIENT OF THIN TYPE OF BUILD—
SKELETON INDRAWN

In conditions of faulty body mechanics, the nonuse of the abdominal muscles allows the pelvis to rotate downward and forward, bringing the sacrum up and back. There results an increased forward lumbar curve with the articular facets of the lumbar spine crowded together in the back.

The dorsal spine curves backward with compression of the dorsal intervertebral discs and the cervical spine curves forward with the articular facets in this region closer together. Therefore, chronic strain of the muscles, ligaments and joints of the spine and pelvis occurs.

Camp Anatomical Supports have an adjustment by means of which their lower sections can be evenly and accurately brought about the major portion of the bony pelvis. When the pelvis is thus steadied, the patient can contract the abdominal muscles with ease and then with slight movement straighten the upper back.

Relieving back strain and fatigue due to faulty body mechanics is a feature of the Camp Support illustrated and other types for Prenatal, Postnatal, Postoperative, Pendulous Abdomen, Visceroptosis, Nephroptosis, Hernia and Orthopedic conditions.

Woman's Auxiliary

HEALTH DAYS PROFITABLE IN MINNESOTA THIS FALL

Mrs. Harold F. Wahlquist

Health Days have been very profitable and fashionable in Minnesota this fall. As president of the State Auxiliary, I have had the privilege of representing our members at meetings in Willmar, Fergus Falls, Crookston, Mankato, and Duluth. Hundreds of citizens from counties in these trade areas flock to High School or Armory auditoriums to hear talks and partake in discussions of their local health problems. Health Days were co-sponsored by the State Auxiliary, the State Medical Association and the State Department of Health. The programs were planned, with the assistance of local committees, to include discussions of health problems particularly relating to immediate community needs. Gov. Luther Youngdahl was a featured speaker at the evening meetings. It is our hope that Mrs. Hobart Johnson, state public relations chairman, will assist in evaluating these meetings for our next issue.

Two County Auxiliaries have joined our forces this fall. McLeod County was organized September 16, with Mrs. A. M. Jensen of Brownton as president, and Clay-Becker, October 6, with Mrs. C. W. Moberg of Detroit Lakes as president. Both Auxiliaries have planned challenging programs for this year, and we are delighted to have them as part of our State Auxiliary.

The following members have been ratified as state standing committee chairmen for the year 1948-49:

Regional Advisers: Mrs. C. C. Allen, Austin, first district; Mrs. S. A. Slater, Worthington, second; Mrs. O. B. Fesenmaier, New Ulm, third; Mrs. A. A. Passer, Olivia, fourth; Mrs. C. Harry Ghent, Saint Paul, fifth; Mrs. Frederick H. K. Schaaf, Minneapolis, sixth; Mrs. R. N. Jones, Saint Cloud, seventh; Mrs. C. L. Oppegaard, Crookston, eighth; Mrs. Anthony J. Bianco, Duluth, ninth.

Advisory Committee: Mrs. Martin Nordland, Minneapolis; Mrs. E. V. Goltz, Saint Paul; Mrs. J. F. Norman, Crookston; Mrs. M. A. Nicholson, Duluth; Mrs. Melvin Henderson, Rochester.

Committee Chairmen: Mrs. Howard Satterlee, Lewiston, Archives; Mrs. W. H. Von Der Weyer, Saint Paul, Bulletin; Mrs. Mark E. Ryan, Saint Paul, Cancer; Mrs. Benjamin Souster, Saint Paul, Editor—MINNESOTA MEDICINE; Mrs. Bernard O'Reilley, Saint Paul, Emergency Nursing; Mrs. Joseph M. Neal, Saint Paul, Finance; Mrs. C. L. Sheedy, Austin, Hygeia; Mrs. Elmer Rusten, Wayzata, Legislation; Mrs. Harlow Hanson, Minneapolis, Medical and Surgical Relief; Mrs. H. E. Bakkila, Duluth, Organization; Mrs. N. O. Pearce, Minneapolis, Press and Publicity; Mrs. A. Christiansen, Saint Paul, Printing; Mrs. David Halpern, Brewster, Program and Health Education; Mrs. Hobart Johnson, Mankato, Public Relations; Mrs. F. W. Franchere, Lake Crystal, Resolutions; Mrs. Neil Dungay, Northfield, Revisions; Mrs. O. I. Sohlberg, Saint Paul, Mrs. Karl Wold, Saint Paul, Mrs. W. N. Graves, Duluth, Mrs. M. McC. Fischer, Duluth, Mrs. A. N. Bessesen, Jr., Minneapolis, Mrs. A. E. Cardle, Minneapolis, Mrs. L. P. Powell, Rochester, Social.

Special Committees: Mrs. Leonard S. Arling, Minneapolis, News Letter; Mrs. Walter K. Haven, Minneapolis, Workshop; Mrs. Harold G. Benjamin, Saint Louis Park, Roster; Mrs. S. S. Hesselgrave, Center City, Parliamentarian.

State Medical Advisory Council: Dr. Gaylord Anderson, Saint Paul; Dr. R. N. Barr, Minneapolis; Dr. Reuben Erickson, Minneapolis; Dr. Fred Magney, Duluth; R. R. Rosell, Saint Paul.

HEALTH WORKSHOP HELD SEPTEMBER 24

Mrs. Leonard Arling

Minnesota physicians' wives held an all-day Workshop, September 24, at the Hotel Radisson, to perfect themselves in their role of medical public relations workers.

Urged by Dr. A. E. Cardle, president of the Minnesota State Medical Association, to refrain from putting Auxiliary work on a "tea party level," and to inform themselves to "speak upon such issues as socialized medicine," they were told that the government has spent $75,000,000 trying to indoctrinate the people of this country with the idea of socalized medicine and that only through the efforts of those far-sighted enough to realize the inevitable results of compulsory health insurance, will the idea be defeated.

Amplifying the responsibilities of the Auxiliary, Lawrence W. Rember, executive assistant, American Medical Association, declared, "Personal contact is not enough. You must employ the channels of mass communication."

"Raise your voice, cast your ballot," he continued. "Make sure the voice of medicine is speaking as one." Mr. Rember advocated state medical journals and other publications as good sources of information and complimented the Minnesota Auxiliary on its Workshop plan—"the first I've heard of anywhere in the nation."

He added that the Auxiliary had assumed national importance as a pioneer in public relations work through the leadership of Mrs. Harold F. Wahlquist, who retired from her post as national chairman of public relations to accept the State Auxiliary presidency.

The women were asked by Reuben F. Erickson, M.D., chairman of the Minnesota State Medical Association's Committee on Public Policy, to adopt the committee's five-point program: (1) information and education for the public, (2) co-operation with other professional and lay groups, (3) encouragement of agencies promot-

Exemplary Laboratory Conditions

Rigid Quality Control

Expert scientific supervision marks each step in the manufacture of all products in the complete, new Laurel line of ethical pharmaceuticals. Parenterals, capsules and enteric coated and compressed tablets are tested for uniformity of quality, with a separate laboratory control number for every product. The Laurel line is manufactured by Goodrich-Gamble, for over 50 years the standard of pharmaceutic excellence.

GOODRICH-GAMBLE
Pharmaceutical Manufacturers
ST. PAUL, MINNESOTA

Laurel

GOODRICH-GAMBLE COMPANY, ST. PAUL, MINNESOTA

(Continued from Page 1258)

ing voluntary prepayment for sickness insurance, (4) opposition of all legislation injurious to the best type of medical practice in Minnesota, and (5) uniting in the promotion of legislation which will further the best type of medical and hospital care.

Dr. Erickson specified four points to consider in prepayment plans for sickness insurance: free choice of physician, the doctor-patient relationship, highest type medical care, representation of physicians on the governing board.

Round tables on Auxiliary organization techniques closed the morning session and, following the luncheon, the Auxiliary resumed general sessions with a panel discussion on "Mediums for Furthering the Community Health Program." Miss Margaret Reagen, director of public relations, Minnesota Hospital Service, and Minnesota Medical Service Associations, moderated the discussions. Participants were: Gisela Konopka, University of Minnesota professor; Otto Silha, promotion Manager, Minneapolis *Star-Tribune;* Ben Leighton, KSTP; Thomas G. Hull, Ph.D., director, Bureau of Exhibits, American Medical Association; William Griffiths, director, public health education, Minnesota Department of Health; Paul C. Leck, M.D., chairman, committee on Rural Medical Service, Minnesota State Medical Association.

At the dinner meeting, Auxiliary members were guests of the State Medical Association and heard John O. Christianson, D.Sc., superintendent of the University of Minnesota's School of Agriculture, describe his recent European tour. Briefly noting conditions abroad, Dr. Christianson defined Communism as "a mental disease." "We must keep ourselves strong," he asserted. "We have so much to learn and so little time left."

Mrs. Luther H. Kice, national Auxiliary president, commended the organization for its "eager and serious efforts on behalf of the medical profession" and told members of the Auxiliary that "the eyes of the world are on this organization."

ROUND-TABLE DISCUSSIONS INCLUDED IN WORKSHOP

Mrs. David J. Halpern

Seeking the means for a firmer relation between the medical profession and the public, Auxiliary members held a round-table discussion on Program and Health Education during the day-long Auxiliary Workshop, September 24.

At the session the women resolved to become acquainted with every doctor's wife in their communities and to equip themselves with information concerning the medical profession. Typical of the information necessary, it was agreed, are the following: medical and health legislation, national health problems, mental hygiene clinics in rural areas, prepayment health plans, the AMA ten-point program, use of animals in medical experimentation, programs of national health organizations, such as tuberculosis, infantile paralysis and cancer, the rural health program of the Medical Association.

Sources of such information were listed as: packet sent to all County Auxiliaries, complete condensation of legislation of the 80th Congress, *Hygeia* magazine, the *Bulletin of the Woman's Auxiliary to the American Medical Association,* the *News Letters* sent by Mrs. Wahlquist and her committee.

Two programs which the women felt deserved their immedate attention were: the recruitment of nurses and the promotion of a radio-speaking project for junior and senior high school students on "What You Can Do About Tuberculosis." (The ten best scripts will be broadcast over WCCO and local stations.) Recruitment of nurses may be implemented by radio programs, posters, literature to counsellors in high schools, movies, sponsoring of scholarships, distribution of new brochure available from the Minnesota Nurses Association. Doctors' wives are planning teas at local hospitals, with tours to follow and agreed to seek the co-operation of druggists, the Farm Bureau, and other groups and organizations.

SOUTHWESTERN AUXILIARY HOLDS SIX-COUNTY MEETING

Mrs. O. M. Heiberg

The Auxiliary to the Southwetsern Minnesota Medical Society invited members of the Business and Professional Women's Club, the American Association of University Women and the League of Women Voters from this six-county area, as well as nurses from the Ninth District Nurses Association to hear Mrs. Elmer Rusten of Minneapolis speak on October 11, on important health legislation. A social hour followed. Among the guests of honor were: Mrs. Harold F. Wahlquist, president of the Woman's Auxiliary to the Minnesota State Medical Association, and Mrs. C. C. Allen of Austin, regional adviser, first district.

The responsibility for planning and providing adequate hospital facilities for the tuberculous is a public, not a private obligation.—A. W. Fiske (Ohio State Representative) *Ohio Pub. Health,* September, 1948.

In Memoriam

ANDREW B. RIVERS

Dr. Andrew B. Rivers, fifty-three years old, died suddenly of a heart attack, October 3, 1948, while attending Mass at St. Mary's Hospital chapel.

Dr. Rivers was a native of Rollingstone, in Winona County, where he was born December 10, 1894. He entered the Mayo Foundation as a fellow in medicine, January 15, 1920, and was appointed first assistant in medicine, July 1, 1923. Later he was named associate in medicine, his main interest being gastroenterology.

He attended St. Francis College, St. Francis, Wisconsin, from 1906 to 1913, and received the M.D. degree in 1917 from Creighton University. He served as an intern at the City and County Hospital in Saint Paul until October, 1918, when he entered the medical corps of the United States Navy as a lieutenant and was stationed at the marine barracks at Norfolk, Virginia.

After the war, Dr. Rivers was an assistant in medicine at the University of Minnesota until he came to Rochester in 1920.

In World War II, Dr. Rivers commanded the medical battalion of the Minnesota defense force with the rank of lieutenant colonel. Functioning with the medical battalion was the nurse corps battalion including units in Minneapolis, Saint Paul, Duluth and Rochester.

He was appointed commanding officer of the state battalion by Adjutant General E. A. Walsh.

Close friends of Dr. Rivers included prominent Notre Dame football coaches, the late Knute Rockne, Hunk Anderson and Frank Leahy, present coach.

In 1929, he received the degree of M.S. in medicine from the University of Minnesota and of M.A. from St. Francis College in 1930. He was a fellow of the American College of Physicians and American Medical Association and member of the American Gastro-Enterological Association, Olmsted-Houston-Fillmore-Dodge County Medical Society, and the Minnesota State Medical Association. He was also a member of the Clinical Research Club, Sigma Xi, Phi Beta Pi and Alumni Association of the Mayo Foundation.

In November, 1927, he married Madalyn D. Smith of Hillsboro, Texas. Mrs. Rivers survives him; also a daughter, Marilyn, student at the University of Minnesota, and a sister, Angela Rivers, of Rollingstone.

LUDVIG R. LIMA

Dr. Ludwig R. Lima of Montevideo, Minnesota, died of a heart attack on September 4, 1948, at his home.

Dr. Lima was born at Stavanger, Norway, on April 30, 1877. At the age of seventeen, he came to this country to join two brothers who were farming near Coopers-

Fifth CHICAGO MEDICAL SOCIETY ANNUAL CLINICAL CONFERENCE

March 1, 2, 3, 4, 1949

PALMER HOUSE • CHICAGO

A scientific program planned to bring information concerning newer developments in all fields of medicine and presented by a group of outstanding speakers.

A wide range of scientific exhibits which promise to be of special interest. Time given for viewing the well displayed technical exhibits. Luncheon round tables where your questions will be answered.

Make your reservations at the PALMER HOUSE

town, North Dakota. He received his education at Sandness, Norway, and at Augsburg College in Minneapolis, where he received the degree of B.A. in 1899. He graduated from Hamline Medical College in 1903 and interned at the City and County Hospital in Saint Paul.

On September 25, 1904, he was married to Constance Bergh at Audubon, Minnesota, and practiced for a year at Everett, Washington. He then located at Montevideo. Three years later he spent a year in postgraduate study in Vienna. During World War I, he served in the army medical corps. Dr. Lima was a member of the Camp Release Medical Society, the Minnesota State and American Medical Associations.

He is survived by his widow, a son, Dr. L. R. Lima, Jr., of Montevideo, and two daughters, Mrs. William Owens of Montevideo and Mrs. Brunhild Brown of Minneapolis.

JOHN THEODORE SCHLESSELMAN

Dr. J. T. Schlesselman of Mankato, Minnesota, died suddenly from a heart attack on September 6, 1948. He had been a prominent eye, ear, nose and throat specialist and civic leader for many years.

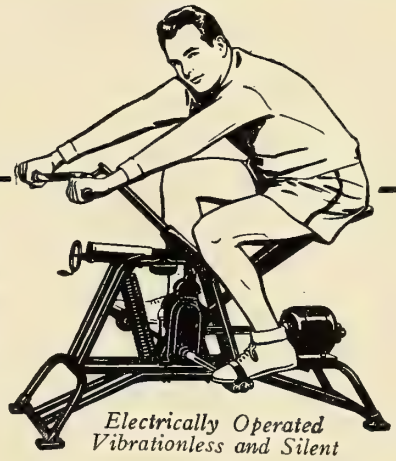
Dr. Schlesselman was born in Reynolds, Indiana, January 21, 1877. He obtained a B.S. degree from Concordia College, Fort Wayne, Indiana, in 1890, and his M.D. degree from the Cleveland University of Medicine and Surgery in 1898. His internship was served at the Huron Street Hospital in Cleveland.

From 1900 to 1920, he practiced at Good Thunder, Minnesota, taking postgraduate work in the Chicago Eye, Ear, Nose and Throat College in 1914, at the New York Postgraduate Medical School in 1915, at the Manhattan Eye, Ear, Nose and Throat College in 1919. In 1926 he spent three months in Vienna.

Dr. Schlesselman was president of the Southern Minnesota Medical Association in 1931 and a former president of the Blue Earth County Medical Society.

In July, 1948, he completed fifty years of practice.

Dr. Schlesselman was married on September 3, 1903, to Elsa Darge, who survives him, as do also two sons, Harold R. Schlesselman of Mankato and Dr. Edward A. Schlesselman of Fresno, California. A brother, George H. Schlesselman, practices in Anoka.



Dr. Schlesselman was much interested in reforestation and was considered an authority on the subject. He was active in Mankato community affairs, having served as president of the Mankato Chamber of Commerce in 1936 and 1937, and as president of the Mankato Lions Club in 1931 and 1932. He was a member of the Lutheran Church.

DAVID L. TILDERQUIST

Dr. David L. Tilderquist, a physician in Duluth for the past forty-four years, died September 29, 1948, at the age of seventy-six.

Born in Vasa, Minnesota, October 22, 1871, Dr. Tilderquist attended Gustavus Adolphus College and the University of Minnesota, where he received his medical degree in 1903. In 1910, he took postgraduate work in

ACTION of the body muscles keeps the body fit the EXERCYCLE* way

Electrically Operated
Vibrationless and Silent

● **Many physicians use Exercycle to limber up, strengthen abdominal muscles, accelerate muscular activity. Just get on, turn the switch and enjoy the beneficial motions of horseback riding, rowing, cycling, swimming. Also excellent for establishing a regimen for patients who are limited as to the amount or kind of activity they can take. Pleasant, convenient, adaptable. Enjoyed by men and women alike. Send for interesting brochure.**

Vienna. He served as chief of the eye, ear, nose and throat services at Saint Luke's and Saint Mary's Hospitals in Duluth.

Dr. Tilderquist belonged to the Saint Louis County Medical Society, the Minnesota State and American Medical Associations, was a member of the American Academy of Ophthalmology and at the time of his death was vice president of the Minnesota Academy of Ophthalmology. He was also a past president of the organization.

He was active in church work and served on the board of foreign missions of the Augustana Lutheran church. For his contributions to special scholarship funds at Gustavus Adolphus College, he was presented with the Greater Gustavus Association award.

Dr. Tilderquist is survived by three sisters, Eva and Ida of Duluth and Mrs. Ernest Rupert of Seattle, Washington.

MELVIN A. VOGTEL

Dr. Melvin A. Vogtel, of Minneapolis, passed away August 30, 1948, at the age of fifty-eight.

Dr. Vogtel was born in New Ulm, September 26, 1891. After graduating from Rush Medical College in 1916, he practiced in Winthrop, Minnesota, for two and a half years before moving to Minneapolis.

He was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations, and Phi Gamma Delta, undergraduate medical society.

Dr. Vogtel married Beatrice Black in Chicago on June 10, 1916. He is survived by his widow, his mother, Mrs. Charles Vogtel of New Ulm, a daughter, Mrs. Gerhard Becker of Chicago, and a brother, Harold Vogtel of Fort Worth, Texas.

MORRILL EDWIN WITHROW

Dr. M. E. Withrow, for forty-five years a practitioner at International Falls, Minnesota, died October 12, 1948. He was seventy-eight years of age.

Dr. Withrow was born in Stillwater, August 21, 1870. He obtained his M.D. degree at Hamline Medical School in 1897, and interned at the Minnesota State Prison for two years. He practiced for nine months at Forest Lake, Minnesota, and at Grantsburg, Wisconsin, for a brief period before moving to International Falls in 1903.

He was one time mayor of International Falls and had been health officer since 1908. He was also active in State American Legion affairs and in the Masonic Order. He was a member of the Upper Mississippi Medical Society, the Minnesota State and American Medical Associations.

Dr. Withrow was married to Agatha Mahoney of Anoka. He is survived by his wife, three sons and three daughters.

ERRATUM

Through a regrettable error, we reported in our September issue the death of Dr. Arthur J. G. Henderson of North Saint Paul. We hasten to correct the report, for Dr. Henderson is very much alive. Our apologies are extended to Dr. Henderson. We hope he will sustain no serious embarrassment as the result of our error.

MAY-O-LITE Reduces Reflection Increases Light Transmission

For many, far too many, years wearers of glasses have been handicapped and irritated by surface reflections. Reflections produce confusing, annoying "ghost images" on the lens surface. Reflections also cause eye and mental strain.

You can now minimize this handicap to the point of near-elimination.

You can do it by including May-O-Lite's Low Reflection Lens Coating in your lens prescriptions.

This revolutionary May-O-Lite process reduces surface reflection 75 to 90%—yet increases transmission of light. It increases the life of the lens surface, too—because Low Reflecting Lens Coating hardens the lens surface and helps to reduce surface scratches.

Developed for the armed services during the war to improve image definition in military instruments—our Low Reflection Lens Coating is now available to your patients. It is obtainable through most manufacturing and dispensing opticians. Write for a descriptive pamphlet and a treated sample of glass today.

FEE SCHEDULE

At the request of Dr. Donald McCarthy, Retiring Branch Medical Director of the Veterans Administration, we are publishing a letter written by Dr. Paul B. Magnuson, Chief Medical Director of the Veterans Administration, to Dr. Morris Fishbein, Editor of *The Journal of the American Medical Association,* dated April 27, 1948. The letter appeared in *The Journal of the American Medical Association* of May 22, 1948. It explains the difficulty in establishing a fee schedule satisfactory to physicians throughout the country and to the Veterans Bureau and how the schedule was finally established, and disclaims charges that the Bureau was arbitrary in adopting a schedule.

VETERANS ADMINISTRATION
Washington 25, D. C.
April 27, 1948

Dr. Morris Fishbein
Editor, The Journal AMA
535 North Dearborn Street
Chicago, Illinois

Dear Dr. Fishbein:

It has come to my attention that considerable misunderstanding has developed throughout the medical profession concerning the establishment of fees for medical services to be paid private physicians participating in the so-called "Home Town Medical Care Program for Veterans." It has been contended that the Veterans Administration has arbitrarily established a Fee Schedule which represents the maximum amount which may be paid for any given service and which is, in effect, a National Fee Schedule. It has also been contended that the various State Medical Societies and other interested groups were not consulted when the Fee Schedule was adopted.

In order to clear up any misunderstanding regarding this matter, it is desired to emphasize that my predecessor Dr. Paul R. Hawley, had no intention at any time of establishing a National Schedule of Fees, nor do I contemplate doing so. However, the Fee Schedules originally submitted by the various State Medical Societies, when the "Home Town Medical Care Program" was inaugurated, varied so widely in format, terminology, and fees for similar or identical services, that it was deemed advisable to establish a uniform Fee Schedule Format and to set up tentative fees which could be used as a guide by the various State Medical Societies when submitting their proposals for the furnishing of medical care to veterans.

This uniform Fee Schedule Format was formulated by the Professional Group of National Consultants to the Chief Medical Director. This Group, representing the various specialties in medicine and surgery, is composed of eminent physicians from all parts of the country. Tentative fees were set up in the format after a careful analysis of Pre-Paid Medical Care Plan, Workmen's Compensation and Insurance Fee Schedules, and also the Fee Schedules in effect in the various States having agreements with the Veterans Administration. As was to be expected, considerable variation occurred in the Fee Schedules reviewed.

The Professional Group of National Consultants made

every effort to arrive at fees that were considered to be within reasonable limits and which would, as nearly as possible, allow a uniform provisional fee schedule for use as a guide in facilitating and expediting the preparation of agreements between State Medical Societies and the Veterans Administration.

Further attempt was made to provide for elasticity in the charges for certain operations or other services which seemed to evoke more than average contention by listing the minimum and maximum amounts considered equitable. These items bear the notation "AA," which indicates that the fee for the given service is to be determined by arbitration and agreement between the Veterans Administration and the Medical Society concerned.

May I reiterate that the Veterans Administration Fee Schedule Format is in no sense to be construed as an arbitrary or National Fee Schedule. Furthermore, it is subject to periodic review and such modification as conditions may indicate.

If it meets with your approval, I would appreciate it very much if you could possibly arrange to publish this as an open letter in the *Journal of the American Medical Association.* I should like this to reach all of the physicians throughout the country, and I know of no better way to do it than through the *Journal.*

Very truly yours,
PAUL B. MAGNUSON
Chief Medical Director

Health education is recognized as an essential tool in tuberculosis control. The general public must know the seriousness of the disease and its cost in human misery and money before it will accept its responsibility to support the work financially. Report, Expert Committee on Tuberculosis, Office International de'Hygien Publique, Paris, *Pub. Health Rep.,* May 7, 1948.

Of General Interest

Dr. Earl C. Elkins, consultant in physical medicine at the Mayo Clinic, was named president-elect of the American Congress of Physical Medicine at the twenty-sixth annual meeting of the organization in Washington, D. C., on September 9. He will be inducted as president at the annual meeting in 1949. Dr. Elkins has been a member of the Mayo Clinic staff for ten years.

* * *

Dr. Tracy E. Barber, of the Austin Clinic, has been engaged as the new medical director of the Hormel Company, it was announced on September 7. Dr. Barber succeeds the late Dr. H. B. Allen. A graduate of the Medical College of Temple University, and a naval veteran, Dr. Barber has practiced in Austin since 1946.

* * *

Dr. John F. Fulton, Sterling, professor of physiology at the Yale University School of Medicine, received the decoration of Honorary Officer of the Civil Division of the Most Excellent Order of the British Empire from the British Ambassador to the United States, Sir Oliver Frank, at the British Embassy in Washington, D. C., on July 23, 1948.

* * *

Due to incorrect information, it was stated in the September issue that Dr. Russell J. Kotval, a dentist, was opening a medical-dental clinic in Fairmont with Dr. Jerome L. Behounek, a physician. Further information reveals that Dr. Behounek is a dentist and that Dr. Kotval, a graduate of the University of Minnesota Medical School, is conducting a medical practice at 121½ West Main, Pipestone.

* * *

The second annual meeting of the Minnesota Public Health Conference was held on October 8 at the Saint Paul Hotel in Saint Paul. The main feature of the afternoon session was a panel discussion of "The Establishment of Full-Time Local Health Departments in Minnesota." At the evening banquet the toastmaster was Dr. Mario Fischer, director of public health, Duluth.

* * *

After being associated in practice with Dr. H. B. Ewens in Virginia since 1938, Dr. John S. Siegel announced on September 8 that he was opening offices in Virginia to conduct a private practice. A graduate of the University of Minnesota in 1937, Dr. Siegel has taken postgraduate work at the Cook County Hospital Graduate School of Medicine, the University of Illinois and the University of Minnesota.

* * *

Dr. Ronald W. Barr, formerly of Sioux Falls, South Dakota, began practice in Hills during the first week of September. At first, while still living in Sioux Falls, he was in Hills for only three days each week but has now moved to the Minnesota community, to conduct a daily practice in a newly constructed office. Previous to Dr. Barr's arrival, Hills had been need of a local physician for several years.

* * *

The first meeting of the thirty-eighth semiannual postgraduate extension course of the Lyon-Lincoln Medical Society was held in Marshall on September 21. The lecturer for the evening was Dr. George Usterman, Rochester, who discussed diagnosis and treatment of gastrointestinal diseases. At the second meeting of the course, on September 28, Dr. Haddow M. Keith, Rochester, spoke on "Brain Tumors in Children and Allied Neurological Conditions."

* * *

Dr. Philip S. Hench, Rochester, was one of ten physicians and scientists named at a meeting in Chicago on September 16 to a committee which will guide the medical policies of a newly established Arthritis and Rheumatism Foundation. The Foundation will raise funds for research and treatment of arthritis and rheumatic diseases. Dr. Hench is a past-president of the American Rheumatism Association, which sponsored the meeting at which the committee was named.

* * *

Friends of Dr. Andrew Gullixson, Albert Lea, gathered on September 20 to honor the physician and his wife for their many years of service to the community. Dr. and Mrs. Gullixson planned to leave Albert Lea on September 25 to establish permanent residence in Long Mont.

Dr. Gullixson practiced in the Albert Lea area for more than forty years. During the past few years he has lived in semi-retirement, compiling a book about the medical profession in Freeborn County prior to 1900.

A county-wide free immunization clinic for residents of Wilkin County began on September 13 when the first clinic was held at Breckenridge. On successive days for a week, immunization clinics were conducted in other key cities in the county. Smallpox vaccination and immunization for diphtheria, tetanus and whooping cough were available to all persons from six months of age to twenty-one years. The county-wide clinic was the first of a series and will be conducted every five years.

* * *

The Arlington Municipal Hospital announced the appointment of Dr. Milo A. Youel to its surgical staff early in September. A graduate of the University of Minnesota Medical School in 1939, Dr. Youel interned at the U. S. Naval Hospital in San Diego, California, then served overseas in the navy. He has taken postgraduate training in surgery at the University of Minnesota and at the Minneapolis Veterans Hospital. In Arlington he is associated in practice with Dr. Verne Schulberg.

* * *

A former staff member of the Veterans Hospital at St. Cloud, Dr. M. B. Dahle, purchased the practice of the late Dr. A. A. Passer in Olivia and expected to begin practice there on September 15. Dr. Dahle, a graduate of the University of Chicago, served his internship at Asbury Hospital, Minneapolis, and then practiced at a clinic in Glenwood for three years. After four years of military service, he took postgraduate work in Chicago, then began his duties at the St. Cloud Veterans Hospital.

* * *

Dr. and Mrs. E. Q. Ertel, Ellendale, were honored guests at a testimonial banquet on October 6 on their fortieth anniversary of community service. Many close friends and men in the medical profession from surrounding towns were present, and telegrams of congratulation were received from those who were unable to attend. Dr. and Mrs. Ertel were presented with a number of gifts, and the doctor was the recipient of Citizenship Medals from the local Veterans of Foreign Wars and the American Legion Posts.

* * *

In early September the name of the More Clinic in Eveleth was changed to the More-Ewens Clinic, with the staff increased to six physicians and services extended to Eveleth, Virginia and Gilbert. Reason for the change was the combining of the More Clinic with the clinic previously operated in Virginia by Dr. H. B. Ewens. The staff of the More-Ewens Clinic now includes Dr. Ewens, Dr. F. R. Kotchevar, Dr. M. L. Strathern, Dr. W. C. Lovshin, Dr. Alfred Marcia and Dr. Terrance D. Callan. No change has been made in the name of the More Hospital, which is operated by the More Hospital Association, a nonprofit organization.

* * *

Dr. A. C. Broders, Sr., of the Mayo Clinic, was honored with several scientific and medical memberships in South America on a recent trip. He was made a corresponding member of the Association Medica Argentina and the Asociacion Medica Argentina Sociedad de Anatomia Normaly Pathologica, and an honorary member of the Academia Nacional de Medicina de Buenos Aires and the Sociedad de Anatomia Normaly Pathologica de Chile. He was also made an honorary member of the faculty of biology and medical sciences of the University of Chile, one of five North Americans to receive this honor.

* * *

From January 1, 1948, through September 28, 1948, the Minnesota Department of Health received reports of 804 cases of poliomyelitis in Minnesota, with 44 deaths. Twenty-seven cases in out-of-state residents, with three deaths, were also reported. About 120 of the cases were reported in July, 335 in August, and 325 in September (1-28). In Hennepin County there were 135 cases, in Faribault 88, in Freeborn 83, in Ramsey 69, in Mower 31, in Steele 27, in Rock 25, in Nobles 23, in Stearns 22, in Anoka 19, and in Wright 17. In past years Minnesota has had 912 cases with 105 deaths in 1916, 955 cases with 145 deaths in 1925, 811 cases with 66 deaths in 1931, and 2,881 cases with 226 deaths in 1946.

* * *

Dr. George Freeman, superintendent of the St. Peter State Hospital for twenty-three years, resigned effective October 1 to become superintendent of the state hospital at Warm Springs, Montana. He was succeeded by Dr. Burton P. Grimes, former assistant superintendent of the St. Peter institution.

Dr. Freeman, in moving to Montana, ends forty-two years of service in Minnesota state institutions. He began his career as a staff member at the St. Peter hospital, later became superintendent of the Willmar State Hospital, and in 1925 assumed the superintendency of the St. Peter institution. Dr. Grimes, the new superintendent at St. Peter, has served as assistant superintendent since 1946 and was a member of the medical staff from 1937 to 1940.

* * *

Cottonwood County was awarded accreditation certificates for its accomplishments in tuberculosis control at a ceremony in Windom on September 21. Dr. S. A. Slater, superintendent of the Southwestern Minnesota Sanatorium, presented certificates awarded by the Minnesota State Medical Association and the Minnesota Department of Health, while special Christmas Seal plaques were presented by Dr. E. A. Meyerding, executive secretary of the Minnesota Public Health Association. A county is accredited when its tuberculosis death rate drops to an average of 10 or less per 100,000 population for a five-year period and when not more than 15 per cent of its high school seniors react positively to the tuberculin test. Cottonwood is the sixteenth county in Minnesota to be so accredited.

* * *

The Hospital Clinic at Austin has a new member on its staff, Dr. H. P. Limbacher, who is the surgeon for the group. Dr. Limbacher interned at Saint Luke's Hospital, Cleveland, and served a residency at Lakewood City Hospital, Lakewood, Ohio. He served three of his five years in the Army in World War II in the European theater. He has qualified for the American College of Surgeons and the American Board of Surgery having completed a two-year fellowship in general surgery at the Cleveland Clinic and then terminating his training as a surgical resident of the Cleveland State Hospital which is affiliated with the department of surgery of the Western Reserve University. He is a member of Theta Kappa Psi medical fraternity, the Cleveland Academy of Medicine and the Ohio State Medical Association.

* * *

Dr. Thomas J. Kinsella of Minneapolis has been elected president of the Mayo Foundation Alumni Association. He succeeds Dr. E. E. Larson of Los Angeles. Dr. Donald C. Balfour again was named honorary president. The new first vice president is Dr. John M. Fallon, Worcester, Massachusetts, and the new second vice president, Dr. John L. Kleinheksel, Wichita, Kansas. Dr. James F. Weir and Dr. Edward S. Judd, both of Roch-

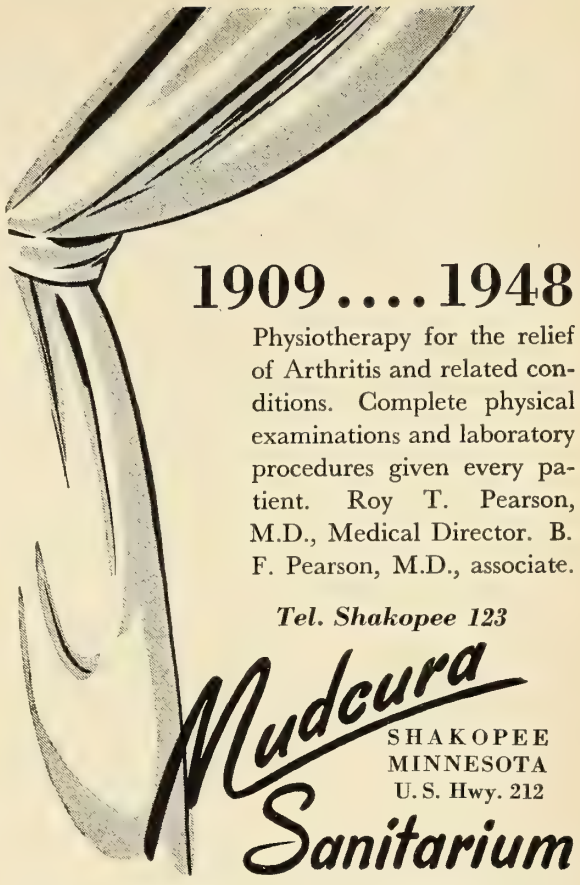
Among Minnesota physicians who attended a two-week continuation course in psychosomatic medicine at the University of Minnesota during the latter part of September were Dr. Russel E. Carlson, Stillwater; Dr. Sidney F. Becker, Bemidji; Dr. Donald S. Branham, Albert Lea; Dr. J. L. Baker, Fergus Falls; Dr. R. F. Mears, Northfield; Dr. Rudolph Wilkowske, Owatonna, and Dr. A. F. Risser, Stewartville.



Subjects covered in the course, which was under the direction of Dr. George N. Aagaard, director of postgraduate medical education at the University of Minnesota, included emotional growth and development, child-parent relationships, the concept of normal and neurotic anxiety, the structure and meaning of a neurosis, symptoms of neurotic maladjustment, the psychological aspects of physical disease, and the fundamentals of psychotherapy.

* * *

It was announced early in September that seven Minneapolis physicians had begun practice in the city.

Dr. Martin A. Nordland, after completing a fellowship in surgery at the Mayo Foundation, became associated with his father, Dr. Martin Nordland, with offices at 1737 Medical Arts Building. Dr. Robert F. Deranleau became associated with Dr. Paul N. Larson and Dr. William B. Stromme in the practice of obstetrics and gynecology at 731 Medical Arts Building. Dr. Norman Schneidman, after completing graduate work at the University of Minnesota and the Veterans Hospital, began practice in internal medicine at 701 Physicians and Surgeons Building.

Four other physicians who opened new offices were Dr. Robert W. Cranston, 1009 Nicollet Avenue; Dr. David Gaviser, 350 Medical Arts Building; Dr. John W. Johnson, 751 Medical Arts Building, and Dr. Fabian J. McCaffrey, 100 E. Franklin Avenue.

MINNESOTA DEPARTMENT OF HEALTH

Dr. Frederick W. Behmler, Morris, Stevens County health officer and member of the State Board of Health, was elected first vice president of the Minnesota Public Health Conference at its second annual meeting, held in Saint Paul, October 8. Dr. C. G. Sheppard, Hutchinson, was re-elected as treasurer for a second year. Dr. Hermina Hartig, chief school physician, Minneapolis Public Schools, was named as a member of the executive committee.

Honorary membership in the conference was bestowed upon Dr. Charles Scofield of Benson, in recognition of his long service as a general practitioner of medicine in Minnesota. Dr. Scofield has practiced in the state for sixty-four years and is now over ninety years of age.

Dr. J. Lawrence McLeod, Grand Rapids, Minnesota, retiring president, presided at the business session of the Conference and also at the evening session, when he gave the presidential address. Greetings from the Minnesota State Medical Association were presented by Dr. E. M. Hammes of Saint Paul, president-elect of the Association. Dr. D. A. Dukelow of Minneapolis, director, Health Division, Community Chest and Council of Hennepin County, presided at a panel discussion on "Full-time Local Health Departments in Minnesota." Other Minnesota physicians participating in the Conference were Drs. Ruth E. Boynton, A. J. Chesley, George Snyder, and Mario Fischer.

* * *

Many health officers and other physicians in all sections of Minnesota have contributed to the success of the five regional Health Days held this fall, the Minnesota Department of Health reports. Beginning early in September, Health Days have been held in Willmar, Fergus Falls, Crookston, Mankato, and Duluth, under the joint auspices of the medical societies, the women's auxiliaries, and the district offices of the Health Department.

Dr. B. J. Branton, Willmar, was general chairman of West Central Minnesota Health Day, held in Willmar, September 9. Dr. W. L. Burnap, Fergus Falls, Minnesota State Medical Association councilor for the 8th

district, was chairman of Park Region Health Day, held in Fergus Falls, September 29. Red River Valley Health Day, which took place in Crookston, October 7, was presided over by Dr. R. O. Sather, who is secretary of the Red River Valley Medical Association. Visitors were officially welcomed to Red River Valley Health Day by Dr. M. J. Bechtel, Warren, president of the medical society in that district.

In Mankato, where South Central Minnesota Health Day was held on October 13, Dr. A. G. Liedloff presided, and Dr. A. E. Sohmer gave an address of welcome. Dr. Liedloff is director of District Unit No. 2, Minnesota Department of Health. Dr. Sohmer is councilor for the 4th district, Minnesota State Medical Association. Dr. P. S. Rudie of Duluth, president of the St. Louis County Medical Society, presided at the Northwestern Minnesota Community Health Day, held in Duluth, October 15.

Other physicians who gave talks or participated in panel discussions at the various Health Days included the following:

West Central: Dr. F. W. Behmler, Morris, Stevens County health officer and member of the State Board of Health; Dr. W. W. Yeager, Marshall, Lyon County health officer; Dr. B. O. Mork, Jr., Worthington, director, district Health Unit No. 5; Dr. Kathleen Jordan, Granite Falls; Dr. Stanley Lindley, superintendent, Willmar State Hospital; Dr. Lloyd Gilman, Willmar, president, Kandiyohi-Swift-Meeker County Medical Society; Dr. A. E. Cardle, Minneapolis, president, Minnesota State Medical Association.

Park Region: Dr. Edward Dyer Anderson, Minneapolis; Dr. Ruth Hill, Moorhead; Dr. H. B. Thompson, Fergus Falls; Dr. Lillian Parsons, Elbow Lake; Dr. James Oliver, Moorhead, president, Clay-Becker Medical Society; Dr. C. O. Estrem, Fergus Falls; Dr. I. E. Bigler, Perham.

Red River Valley: Dr. O. D. Mellby, health officer, Thief River Falls; Dr. M. O. Oppegaard, mayor of Crookston.

South Central: Dr. B. P. Grimes, superintendent, St. Peter State Hospital; Dr. C. G. Sheppard, Hutchinson, McLeod County health officer; Dr. A. D. Mattson, St. James; Dr. Paul C. Leck, Austin, chairman, Rural Health Committee, Minnesota State Medical Association; Dr. F. F. Callahan, Saint Paul, chief of Medical Services unit, Division of Social Welfare; Dr. A. F. Dysterheft, Gaylord, Sibley County health officer; Dr. Paul Dwan, Minneapolis, president, Minnesota Heart Association; Dr. E. E. Novak, New Prague, Le Sueur County medical advisory committee and member of the Board of Regents, University of Minnesota.

Northeast: Dr. L. R. Gowan, Duluth; Dr. R. H. Pumala, Cloquet; Dr. J. D. Van Valkenberg, Floodwood; Dr. F. R. Kotchevar, Eveleth; Dr. John K. Butler, Carlton; Dr. Clarence Jacobson, Chisholm; Dr. E. L. Tuohy, Duluth; Dr. G. A. Hedberg, superintendent of Nopeming sanatorium; Dr. W. S. Neff, Virginia.

Also contributing to one or more Health Day programs were Dr. A. J. Chesley, executive officer, Minnesota State Board of Health; Dr. Gaylord W. Anderson, director of the School of Public Health, University of Minnesota; Dr. Mario Fischer, director of the Duluth Health Department and of Health District No. 4; Doctors Robert N. Barr, Helen Knudsen, A. B. Rosenfield, and Dean S. Fleming, of the State Department of Health staff; and Dr. Donald A. Dukelow, director of medical services, Minneapolis Council of Social Agencies.

BLUE SHIELD NEWS

Applications received for Blue Shield to Sept. 30, 1948....90,132
Blue Shield cases paid, Sept. 1-Sept. 30, 1948..... 433
Total for 1948..... 1,847
Paid on Blue Shield cases, Sept. 1-Sept. 30, 1948....$16,391.14
Total for 1948.....$68,968.61

During the last few months, the growth of Blue Shield in Minnesota has been truly great. Along with the increased number of Minnesota citizens protected by Blue Shield there has been an increase in the number of services for which allowances have been made as well as the amount allowed. As a result of these increases the Blue Shield has had many compliments. These "sunshine letters" have been written on expensive bond letterheads, on inexpensive ten-cent store tablets, and one very flowery and colorful thank-you card has been received. Irrespective of what the writing material consists of, the one theme goes like this:

"When we were suddenly stricken with illness in our family, we were very glad we had Blue Shield. I wish to thank you very much for the very generous allowance you made to our doctor and also for the prompt attention given my case."

Letters of this sort are deeply appreciated, and it is felt that these "sunshine" letters should be passed on to the persons responsible, namely—the physicians of Minnesota who are supporting the Blue Shield. The Blue Shield office may be set up to operate with the utmost efficiency, but it cannot do so without the aid of the physicians, and the office is getting this aid.

The Blue Shield subscriber appreciates the physicians' showing the Blue Shield allowance on the statement, billing the limited subscriber for the balance due, or in the case of the unlimited subscriber, sending a statement indicating that the Blue Shield allowance is payment in full. They appreciate the fact that their own family doctor or the doctor to whom they are referred by the family doctor is a Blue Shield participating doctor of medicine, for they feel that if the doctor whom they respect and admire is back of a plan to which they have subscribed, it is worth while. Thus, actually "sunshine" letters received in the Blue Shield office are not thanking the office personnel, but are expressing their thanks to the people behind the Blue Shield—the doctors of Minnesota.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

YOUR BABY. Gladys Denny Shultz, contributing editor, Ladies' Home Journal, and Lee Forrest Hill, M.D., former president, American Academy of Pediatrics. 278 pages. Illus. Price $3.50, cloth. New York: Doubleday & Co., 1948.

OCCUPATIONAL THERAPY SOURCE BOOK. Edited by Sidney Licht, M.D. 90 pages. Price $1.00, cloth. Baltimore: Williams & Wilkins Co., 1948.

ESSAYS IN BIOLOGY. Presented to Arthur Neville Burkitt. A collection of essays written by some of his pupils to celebrate his completion of twenty-one years as Head of the Department of Anatomy, University of Sydney. 163 pages. Illus. Paper cover. Australia: Australasian Medical Publishing Co., Ltd., Glebe, New South Wales, 1948.

HUMAN BIOCHEMISTRY. Second edition. Israel S. Kleiner, Ph.D. Professor of Biochemistry and Director of Department of Physiology and Biochemistry New York Medical College, Flower and Fifth Avenue Hospitals; formerly Associate, the Rockefeller Institute for Medical Research, New York. 649 pages. Illus. Price $7.00, cloth. St. Louis: C. V. Mosby Co., 1948.

TECHNIQUE OF TREATMENT FOR THE CEREBRAL PALSY CHILD. Paula F. Egel, Cerberal Palsy Director, Children's Hospital, Buffalo, N. Y. 203 pages. Illus. Price $3.50, cloth. St. Louis: C. V. Mosby Co., 1948.

PHYSICIAN'S HANDBOOK. Fifth Edition. John Warkentin, Ph.D., M.D., and Jack D. Lange, M.S., M.D. 293 pages. Illus. Price $2.00, flexible binding. Palo Alto, California: University Medical Publishers, 1948.

SYMPOSIA ON NUTRITION. Volume 1, Nutritional Anemia. Edited by Arthur Lejwa. 194 pages. Illus. No charge. Cincinnati: Robert Gould Research Foundation, Inc., 1948.

FUNDAMENTALS OF CLINICAL NEUROLOGY. H. Houston Merritt, M.D., Professor of Clinical Neurology, College of Physicians and Surgeons, Columbia University; Chief of Division of Neuropsychiatry, The Montefiore Hospital; Fred A. Mettler, M.D., Ph.D., Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University; and Tracy Jackson Putnam, M.D., Professor of Neurology and Neurological Surgery, College of Physicians and Surgeons, Columbia University. 289 pages. Illustrated. Philadelphia: The Blakiston Company, 1947. Price, $6.00.

This concise and authoritative résumé of fracture treatment will be a welcome handy reference for students and general practitioners. The material is well organized for handy reference.

The illustrations are adequate and clear.

—S. W. Shimonek, M.D.

HANDBOOK ON FRACTURES. Duncan Eve, Jr., M.D., F.A.C.S., Surgeon-in-Chief, Nashville, Chattanooga and St. Louis Railroad; District Surgeon, Louisville and Nashville Railroad; Associate Professor of Surgery, Vanderbilt University School of Medicine; Member of the Southern Surgical Society; Member of The American Association for the Surgery of Trauma; Chairman of the Committee on Fractures of the Medical and Surgical Section of the American Railroad Association; Member of the Committee on Fractures of the American College of Surgeons; Attending Surgeon, St. Thomas Hospital, Nashville, Tennessee, in collaboration with Trimble Sharber, A.B., M.D., Attending Surgeon, St. Thomas Hospital, Nashville, Tennessee. 263 pages. Illustrated. St. Louis: C. V. Mosby Co., 1947. Price: $5.00.

This is an interesting, well written book of less than 300 pages that combines a brief review of neuro-anatomy and physiology with the clinical aspects of neurology. The first portion dealing with examination of the nervous system covers particularly well the cranial nerves. One might wish for more attention to the testing of peripheral nerves, and especially the inclusion of some diagrams of nerve injury.

The remainder of the book deals with anatomic diagnosis. It does this by considering the nervous system segmentally: peripheral nerves, spinal cord, brain stem, et cetera. In each subdivision after covering the anatomy, blood supply, and physiology, there is a brief consideration of diseases and clinical syndromes. In a book this brief there is little space given to details of therapy, but the chief therapeutic agents are mentioned. A valuable chapter is the one on cerebro-spinal fluid giving an extensive listing of cerebro-spinal fluid changes in various diseases.

ENCYCLOPEDIA OF MEDICAL SOURCES. Emerson Crosby Kelly, M.D., F.A.C.S., Associate Professor of Surgery, Albany Medical College; Attending Surgeon, Albany Hospital; Editor, Medical Classics. 476 pages. Baltimore; Williams & Wilkins Co., 1948. Price $7.50.

All persons doing reference work at some time or another are led astray and must retrace their steps because of incomplete or inaccurate citations to original work. Medical eponyms slow down, and frequently stump, the searcher.

Dr. Kelly, having had these experiences as an author and editor, began to keep a record of references to medical eponyms and to original and classic reports. After verifying each item and accurately recording these references, he has published them so that others may benefit from his findings.

The contents of the book are arranged alphabetically by author, with each identified as to nationality, specialty and dates. Under each author's name is a concise phrase describing his noteworthy contribution, or contributions, to medical literature with the exact title and reference for each. Useful cross references are scattered throughout and there is a subject index in the back of the book.

Dr. Kelly made no attempt to assign priority in descriptions. His search was for the correct titles and exact references to what, in his opinion, are the earliest or the most outstanding contributions to a subject.

While, no doubt, many a reference will have been missed in compiling this book, the author has included over 5,000 names and 15,000 references.

This is a useful reference tool in a medical library where time-saving devices are appreciated and where accurate, verified references are essential.

M. M. P.

DUODENAL ULCER: A SOCIOPSYCHOLOGICAL STUDY OF NAVAL ENLISTED PERSONNEL AND CIVILIANS, Jurgen Ruesch, M.D., and others. University of California Press. Price, $4.00.

The book reports the results of an investigation of the social and psychological factors in duodenal ulcer patients. Special emphasis is placed on situational difficulties and their relation to the individual's character structure.

Dr. Ruesch is associate professor of psychiatry in the University of California Medical School and research psychiatrist at the Langley Porter Clinic, San Francisco. The book was written in collaboration with Robert E. Harris, Ph.D., Carole Christiansen, M.A., Martin B. Loeb, B.A., Sally Dewees, M.S., and Annemarie Jacobson, M.D.

This baby's mother learned about Mead's Oleum Percomorphum from her physician, not from public advertising or displays.
"Servamus Fidem"
HOW much sun does the infant really get?
Not very much: (1) When the baby is bundled to protect against weather or (2) when shaded to protect against glare or (3) when the sun does not shine for days at a time. Mead's Oleum Percomorphum is a prophylactic against rickets available 365¼ days in the year, in measurable potency and in controllable dosage. Use the sun, too.
Mead Johnson & Co., Evansville, Ind., U.S.A.

n the field THEELIN has the distinction of being the first estrogen isolated in pure crystalline form and the first to assume clinical importance. Moreover, the early laboratory and clinical work with THEELIN largely formed the groundwork for the entire modern concept of estrogens and their physiological effects.

THEELIN

(a naturally-occurring estrogen)

y experience Firmly rooted in endocrine research, THEELIN has had a strong sound growth *for two decades.* This pioneer estrogen has been successfully employed in *millions* of doses. Thorough appraisal of THEELIN is presented in its bibliography, which now consists of over *400 references in scientific publications*—impressive evidence that THEELIN produces specific effects in relieving symptoms and sequelae of both the natural and the artificial menopause. Being a pure crystalline substance, with potency determined by weight, THEELIN is 100% active estrogen.

Soft Diet
trying your patients' patience?

— try palatable Swift's Strained Meats

Tempting, natural source of complete protein

6 varieties:
Beef, lamb, pork, veal, liver, heart

The things some patients on soft, smooth diets have to eat! It's no wonder appetites lag.

To perk up patients' interest in foods, many doctors now prescribe specially prepared Swift's Strained Meats when soft foods are indicated in a high-protein, low-residue diet. They help two ways. *One*, Swift's Strained Meats taste so good. Few patients can turn down real meat goodness. *Two*, an excellent source of B vitamins, Swift's Strained Meats help restore patients' natural appetite for all foods.

Originally prepared for infant feeding, Swift's Strained Meats are soft, smooth (may easily be used in tube-feeding), slightly salted—cooked to retain all their delicious meat flavor. Six kinds for variety: beef, lamb, pork, veal, liver, heart. Each one 100% meat, they provide an excellent, palatable source of complete, high-quality proteins and hemapoietic iron. These meats make available *simultaneously* all known essential amino acids . . . for optimum protein synthesis. Convenient — Swift's Strained Meats are ready to heat and serve.

The makers of Swift's Strained Meats invite you to send for your copy of "The Importance of Protein Foods in Health and Disease"—a physician's handbook of protein feeding, written by a doctor. Send to:

ACCEPTED COUNCIL ON FOODS AND NUTRITION AMERICAN MEDICAL ASSOCIATION

All nutritional statements in this advertisement are accepted by the Council on Foods and Nutrition of the American Medical Association.

For patients who can take foods of less fine consistency —Swift's Diced Meats offer tender morsels of nutritious meat with tempting flavors patients appreciate.

The $64.00 Question

How much longer do you expect to practice?

Might it be 10, 15 or 20 years?

Will you average $750 a month—$9,000 a year gross income?

Will your aggregate income amount to $90,000—$135,000 or $180,000 or more?

These are Incomes worth Insuring! CAN YOU insure your Income for 20 years?

YES! You can insure against loss of Income up to 80%
For 1 year or for 20 years or EVEN FOR LIFE—

Against Accidental Death, Loss of Hands, Feet or Eyes,
Total Disability—Loss of Time due to Accident or Sickness.

CONTINENTAL'S COMPANION POLICIES, Provide—

1. Hospital Benefits of $20 per day plus
2. Accident and Confining Sick Benefits of $400 a month
3. Total Permanent Disability Benefits of $300 a month
4. Dismemberment Benefits of $5,000 and $300 a month for Life
5. Accidental Death Benefits of $7,500—Travel Acc'd $12,500

SPECIAL FEATURES

No Cancellation Clause, *Standard Provision* 16
No Terminating Age, *Standard Provision* 20
No Increase in Premium, *Once Policy Is Issued*
Grace Period 15 Days

When Whims and Fancies Obstruct Good Nutrition

Often perverted food attitudes and abnormal outlooks regarding foods and nutrition interfere with adequacy in dietary intake or are responsible for nutritionally improper eating habits. Accordingly, excessive amounts of foods one-sided in nutrient content are consumed, or more desirable foods are avoided, to the detriment of the nutritional health.

When such dietary whims and fancies rule, the delicious supplementary food drink, Ovaltine in milk, finds special usefulness for readjusting the daily nutrient intake. Its bounty of nutrients virtually assures complementation of inadequate dietaries to full allowances of required nutrients. Its flavorfulness induces its ready acceptance and continued use.

Ovaltine in milk, three glassfuls daily, supplies the abundance of essential nutrients itemized in the accompanying table. Its protein is biologically complete, the nutrients dietetically are well-proportioned; and it is quickly digested and assimilated for meeting metabolic needs.

THE WANDER COMPANY, 360 N. MICHIGAN AVE., CHICAGO 1, ILL.

Ovaltine

Three servings daily of Ovaltine, each made of ½ oz. of Ovaltine and 8 oz. of whole milk, provide:*

CALORIES	669	VITAMIN A	3000 I.U.
PROTEIN	32.1 Gm	VITAMIN B_1	1.16 mg.
FAT	31.5 Gm	RIBOFLAVIN	2.00 mg.
CARBOHYDRATE	64.8 Gm	NIACIN	6.8 mg.
CALCIUM	1.12 Gm.	VITAMIN C	30.0 mg.

Experience is the Best Teacher

R. J. Reynolds Tobacco Co., Winston-Salem, N. C.

John William Ballantyne

(1861-1923)

proved it in obstetrics

BALLANTYNE, in his early studies of anatomical and pathological conditions found in the new-born, sensed the value of routine prenatal care in obstetrics. At the same time, other obstetricians were beginning to realize the necessity of greater attention during the ante partum period as a result of their investigations of eclampsia. It remained for Ballantyne, however, to be the first to establish a clinic for the expectant mother. World-wide acceptance of his concepts quickly followed Ballantyne's successful experiences in prenatal supervision.

EXPERIENCE IS THE BEST TEACHER IN CIGARETTES, TOO!

Yes, experience *is* the best teacher in choosing a cigarette! Millions of smokers who have tried and compared many different brands of cigarettes have found that Camels suit them best.

Try Camels. See if your *own* taste doesn't appreciate the rich, full flavor of Camels. See if your *own* throat doesn't welcome Camel's cool, cool mildness.

Let your own experience tell you why, with scores of smokers who have tried and compared, Camels are the "Choice of Experience."

According to a Nationwide survey:

More Doctors Smoke CAMELS

than any other cigarette

In a nationwide survey by three independent research organizations, 113,597 doctors were asked to name the cigarette they smoked. More doctors named Camel than any other brand.

The First X-Ray...

Medicine and Dentistry thank Wilhelm C. Röntgen (1845-1923), director of the Physical Institute of the University of Würzburg, for discovery of the X-ray.

A barium platinocyanide screen, glowing brightly in the dark in the course of one of his laboratory experiments with a Hittorf-Crookes tube, put the Bavarian physicist on the trail of the invisible ray.

Further investigation disclosed its great penetrative and photographic powers. His first photograph recorded the bones of Frau Röntgen's hand. A "preliminary communication" on his discovery was released on December 28, 1895, to the president of the Physical Medical Society of Würzburg—and the X-ray, so named by Röntgen for want of anything more definitive, was promptly welcomed in medical and dental circles.

Doctors Today still rely not only upon the X-ray, but also upon another professional safeguard which came into being less than four years after the X-ray itself: the malpractice insurance policy with which The Medical Protective Company assures doctors *complete* protection, *preventive* counsel and *confidential* service.

Even unto the least of these . . .

Normal childhood, a chance to compete and play with other children on equal terms—that is the hope and prayer of *petit mal* victims, and their parents. And that is the cheering prospect which Tridione holds forth. Clinical reports show that a high percentage of cases not amenable to other forms of therapy react favorably to Tridione. In one study, Tridione was given to 166 patients with *petit mal*, myoclonic jerks and akinetic seizures who had not been benefited by other medication.[1] With Tridione, 83% showed fewer seizures. Some of the patients became seizure-free and remained so even after Tridione was withdrawn. Similar results have been reported by other investigators. Thus it is not surprising to find Tridione designated as the drug of choice in the *petit mal* triad. Why not give it a trial in your next *petit mal* case? You may obtain Tridione in 0.15-Gm. *Dulcet** Tablets, in 0.3-Gm. capsules, and in a flavored solution containing 0.15 Gm. per fluidrachm. For literature on Tridione, just drop a line to ABBOTT LABORATORIES, North Chicago, Illinois.

NOW... A Bovie UNIT FOR YOUR OFFICE!

MADE FOR OFFICE USE-- PRICED FOR OFFICE USE!

For All Minor Electrosurgery

Here is a worthy namesake of the larger hospital Bovies, the kind used and preferred by the world's leading surgeons and hospitals. The Office Bovie incorporates many of the outstanding features of the big Bovies—yet it is a doctor's Bovie—a compact, easy-to-use electrosurgical unit made especially for office electrosurgery.

Bovie Spark-gap Cutting as well as Spark-gap Coagulating, plus a special current for epilation are features of this unit. It will perform a host of useful surgical techniques—techniques which will be of invaluable aid in your daily practice. A few of its outstanding uses: COAGULATION OF TONSIL TAGS, ERADICATING SEBACEOUS CYSTS, ABORTING BOILS, DESICCATION OF WARTS, CONIZATION OF CERVIX, ERADICATING SKIN BLEMISHES, EPILATION (destruction of hair follicles in permanent removal of unwanted hair).

Further evidence of the safety of Benzedrine Sulfate therapy

More data, showing that Benzedrine Sulfate, in proper dosage, produced no toxic effects, have lately been published in a study by Caveness.[1]

He gave the drug for 14 consecutive weeks to 23 unselected hospital patients whose ages *averaged 65 years.* Daily dosages over the period ranged from 5 to 30 mg. The author observes:

"... no significant changes were noted in the cardiovascular, urinary, hematopoietic, or respiratory systems ..."

From this study, it would appear that Benzedrine Sulfate may be safely used in the treatment of depression in the aged.

LUMBOSACRAL AILMENTS

An Orthopedic Surgeon* in writing on the treatment of lumbosacral disorders in his book Backache and Sciatic Neuritis states as follows: — "Every patient should be given prolonged conservative treatment before radical measures are considered. Non-operative treatment consists of recumbency in bed, the application of support (adhesive strapping and belts of various types) and physical therapeutic measures. When backache at the lumbosacral junction is uncontrollable by such measures, a fusion operation is recommended."

The Camp Support (illustrated) is a practical, comfortable aid in lumbosacral disorders.

The side lacing adjustment provides a steadying influence upon the pelvic girdle and the lumbosacral articulation. The back is well boned, resting and supporting the lumbar spine.

The garment is easily removed for physical therapeutic treatments.

Symposium on Antibiotics

Minnesota State Medical Association

Tuesday, June 8, 1948

INTRODUCTION TO SYMPOSIUM

WESLEY W. SPINK, M.D.
Minneapolis, Minnesota

FROM time to time at the annual meetings of the Minnesota State Medical Association, the status of specific therapy in infectious diseases has been reviewed. For this and other reasons, it is appropriate that the present position of the antibiotics in clinical medicine should be reviewed. We are indeed fortunate in the three men who have agreed to participate in this symposium. The first speaker, Dr. Sam Boyer, Jr., of Duluth, is well qualified to discuss the "Present Trends in Penicillin Therapy." The second speaker, Dr. Karl H. Pfuetze, has co-operated with the group from the Mayo Clinic in pioneer studies on the effect of streptomycin on the clinical course of tuberculosis. His subject is "Streptomycin in Tuberculosis." Dr. Wallace Herrell, the third speaker, has been identified for many years with the progress of antibiotic therapy in infectious diseases, and is the author of a monograph on penicillin. His subject is "Streptomycin and Newer Antibiotics in the Treatment of Infections Other Than Tuberculosis."

PRESENT TRENDS IN PENICILLIN THERAPY

SAM BOYER, JR., M.D.
Duluth, Minnesota

PRESENT trends in penicillin therapy may be roughly divided into four groups: (1) the promiscuous use of penicillin; (2) inadequate bacteriological study prior to the administration of penicillin; (3) penicillin reactions; and (4) methods and preparations to give prolonged activity of penicillin.

Penicillin is today one of the most widely used drugs. Questioning at the pharmacies of hospitals indicates that it is easily one of the five most commonly prescribed drugs if not the most. The relative innocuousness of the preparation, its definite value in many conditions, and confidence in its effect, on the part of profession and laity alike, have led to this frequent use. Actually, in many cases it is prescribed as freely as our most common analgesics or antipyretics. In a home practice one finds it is given at the first sign of infection and often before a diagnosis may be made. One of my older colleagues, an epidemiologist, recently remarked to me: "Years ago we used to say a patient had a touch of pneumonia,

Read as part of a Symposium on Antibiotics before the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 8, 1948.

give them drug X only to have a case of smallpox develop. Now we say they have a sinus infection, give them penicillin and a few days later have a case of measles."

TABLE I.

Patients Receiving Penicillin	143
Crystalline Penicillin	41
Procaine Penicillin	88
Combined Crystalline and Procaine	14

A review of the patients receiving penicillin covering approximately a three-week period at St. Luke's hospital in Duluth show that in this hospital with an average daily census of 295 patients, 143 received penicillin for one reason or another. It is of interest that about twice as many received procaine penicillin in oil as received crystalline penicillin (Table I). The patients could be divided into the following groups (Table II) with the corresponding number receiving the drug: medical 26, infectious diseases 10, dermatology 4, tuberculosis 2, surgery 24, genitourinary 7, orthopedic 12, gynecologic 12, eye, ear, nose and throat 6, obstetric 26, and unclassified 14. It is of interest that among these 143 patients the diagnoses ran almost the entire gamut of diseases prevalent in this part of the country. The great majority of obstetrical and surgical patients received penicillin prophylactically. The same can be said of the orthopedic and genitourinary cases. In obstetrical and gynecological surgery it was apparently used at times for urinary infections and in surgical cases for fever appearing postoperatively. I do not believe we are in a position to question its use prophylactically, but one might indeed raise the question of whether its use as such is making us more dependent on a valuable drug and less so on our technique. In medicine there again appears to have been rather haphazard use. Here one found it used in two patients with tuberculosis, three with rheumatic fever, in patients with nephrosis, asthmatic bronchitis, and upper respiratory infections. Actually this antibiotic is frequently used when some of our common antipyretics could be just as judiciously and less expensively used and is more often used without a definite diagnosis than with one.

The promiscuous use of penicillin is definitely bound to inadequate bacteriological study. Again in the 143 patients receiving penicillin in this approximate three-week period seven had blood cultures, two had spinal fluid cultures, eight had nose and throat cultures and two had urinary cultures (Table III). It is my belief that where bacteriological studies may be done prior to the administration of such a valuable drug, this

should first be done. It is unusual that a delay of a day or two may do harm. It is, of course, true that in fulminating diseases, like meningitis, immediate use of chemotherapy or antibiotic therapy is of prime importance. However even in these instances blood culture and spinal fluid cultures can easily be first obtained. The establishment of a definite bacteriological diagnosis will give some idea as to whether the drug is indicated, the size of the dosage and how long it should be continued. In country practice, of course, it is recognized that bacteriological study is often a near impossibility. However, some of my friends in active country practice have made full use of the facilities of the State Board of Health in order to obtain such information. I presume one might formulate the dictum: use penicillin wisely and judiciously, and if humanly possible try to get adequate bacteriological study first.

Directly related again to the frequent and promiscuous use of the drug is the popular conception that this antibiotic agent is entirely harmless. It is perfectly true that toxicity and the incidence of reactions is low. However, we have lost sight of two facts: (1) serious and sometimes alarming reactions may occur; and (2) by indiscriminate and frequent use of the antibiotic, the value of the drug in the future if needed for some virulent and life-threatening infection may have become lessened or prohibited. The literature is rife with reports on penicillin reactions. Lyons[17] indicated that chills with or without fever oc-

curred with intravenous injections and, of course, noted the occurrences of thrombophlebitis after intravenous administration. In addition he noted burning pain at the site of injection, headache, faintness, tingling in the testes, muscle cramps and urticaria. The latter occurred in 5.7 per cent of the cases. It was thought that these reactions were due to impurities in the preparations. Eilert[7] classified reactions as (a) toxic dermatitis occurring in patients who had never received penicillin before, and appearing about the tenth day; (b) exfoliative dermatitis and (c) a serum sickness type of reaction manifested by fever, urticaria and polyarthritis or arthralgia. She indicated that the latter type of reaction might occur as late as nine days after penicillin had been discontinued. Peck[20] classified reactions into four groups: (a) those similar to serum sickness and closely allied to which are toxic erythema and severe local reactions following the use of oily preparations; (b) allergic contact dermatitis following local applications; (c) erythematovesicular eruptions usually occurring at the site of previous fungus infections and (d) febrile reactions following the use of aerosols or bronchial instillations.

Strazza,[21] Eisenstadt,[8] Keefer,[15] Hailey,[12] and Hinman[14] all report instances simulating serum sickness. The latter also notes ecchymoses, gastrointestinal symptoms and central nervous system complaints. Binckley and Brockmole[2] report one case of contact sensitivity, and Barker[1] adds a case of dermatitis venenata. Farrington[10] reports cases with definite cutaneous sensitivity and indicates a definite allergic reaction. Criep[5] has, in addition to reporting a case with an urticarial reaction, definitely shown that skin tests, passive transfer tests and precipitin tests may all be positive. Graves[11] et al report immediate reactions to penicillin with the development of a vesicular rash in people who had previous fungus infections and raise the question of (a) fungus antigen relationship; (b) release of toxins by bacterial action; or (c) sensitivity. Bullous dermatitis[19] and also stomatitis[10,16] have been reported. The development of the latter after oral ingestion of penicillin is a very important detail. The sore mouth is very distressing to the patient and the danger is presented of increasing the dose of penicillin and aggravating the condition rather than correcting the lesion by discontinuing the medication.

A discussion of the reactions to penicillin cannot be concluded without reference to the dangers and complications of intrathecal administration which include[22] radiculitis and myelopathy associated with chronic meningeal thickening. Erickson et al[9] cite the following factors in the production of toxic manifestations following intrathecal injection: (a) concentration of penicillin solution; (b) slow diffusion of spinal fluid; (c) size of individual dose; (d) frequency of injection; and (e) duration of intraspinal therapy. Finally, as Morginson[18] has pointed out, there are in addition to the direct toxic reactions and antigen reactions also the therapeutic shock or Jarisch-Herxheimer reaction and the indirect reaction on pathological processes. An attempt has been made to combine the classifications of Eilert, Peck and Morginson in Table IV. It is thus seen that the frequent and injudicious use of penicillin may result in reactions which are deleterious to the patient and which may possibly sensitize them so as to make the future use of penicillin almost an impossibility.

TABLE IV. CLASSIFICATION OF REACTION

1. Direct Toxic Reaction
   - A. Febrile
2. Antigen Reaction
   - A. Similar to serum sickness
   - B. Contact dermatitis
   - C. Erythematovesicular eruptions
   - D. Exfoliative dermatitis
3. Therapeutic Shock
4. Indirect Action on Pathologic Process

It is a far cry from the first dose of penicillin any of us gave or ordered given to the present-day widespread administration. Attempts have been constantly made to refine the drug and to prolong its action. Crossone et al[6] cite the following methods to obtain a concentration above .030 units per c.c., which is generally considered an adequate level: (a) increasing the dosage and administering the drug more frequently; (b) varying the route of administration (constant intravenous or intramuscular drip); (c) slowing absorption by cooling the site of administration or by the administration of penicillin in oil or beeswax; (d) suppressing the excretion in renal tubules by use of various preparations.

Penicillin in beeswax and oil was the first preparation which gave an adequate prolonged blood level. However, pain on injection, the persistence of a subcutaneous or intramuscular mass, allergic reactions and the development of sterile abscesses have complicated its use. Procaine penicillin is the latest preparation, the administration

of which give adequate levels over a twelve- to twenty-four-hour period. The use of this salt in sesame oil has been shown by Herrel[13] and Boger et al[4] to yield blood levels considered adequate in the treatment of pneumonia for twenty-four hours. The advantages in this preparation lie in fewer injections, reduction in pain, reduced man-hours in large-scale administration of the drug in hospitals and ready availability of penicillin for home use. Still faced as a disadvantage, is the intramuscular injection of an oil. Recently advanced is procaine penicillin in aqueous solution. I understand that blood levels similar to those obtained with the oil preparation are obtained. It is entirely possible, although too early to say, that study on a large scale will prove the efficacy of this preparation and thus answer the problem of injecting an oil.

Various preparations have at times been used experimentally to inhibit the excretion of penicillin. Caronamide (carboxyphenylmethanesulfanilide) is the most recent and apparently most successful of these preparations. This drug inhibits the enzyme transport system of the renal tubular epithelium by which penicillin is excreted. Crossone[6] found that when 1.5 to 2 grams of caronamide were administered every four hours the blood penicillin level was elevated two to seven times. Boger[3] later demonstrated that a caronamide plasma concentration level of approximately 15 mg. per cent was necessary to inhibit the renal excretion of penicillin sufficiently to double the blood level of the latter. A dosage of 1.5 gms. every three hours may give this level in some persons, but on the average in the person with normally functioning kidneys a dosage of 3 grams every three hours or 4 grams every four hours is necessary to maintain this desired level. It is thought that the maximum efficiency of this drug is reached between the levels of 20 mgs. to 40 mgs. per cent. This preparation has not been used widely and has only recently, to my knowledge, been made available for general use in this part of the country. Its practical value yet remains to be seen. Its disadvantage lies primarily in the large number of tablets necessary.

In conclusion, penicillin is used promiscuously, widely, and frequently without indication. Bacteriological study and diagnosis are lacking more often than not. Reactions to penicillin, usually allergic, may occur. The development of procaine penicillin during recent months has been a far-reaching step in prolonging the activity of the drug. The inhibition of renal excretion may be of value in the prolongation of penicillin activity.

MENTAL AND SOCIAL HEALTH

Malaria, smallpox, tuberculosis, venereal disease, diphtheria, many others, could all be got rid of—from the whole world, without any further knowledge or research, if we had mental health and social health in the people of the world, if enough people in enough places could think in factual terms and had good mental health. Nothing keeps the diseases alive except ignorance and shortsighted self-interest. Long-sightedness would get rid of those things quickly.—Brock Chisholm, M.D., *Mental Hygiene*, July, 1948.

STREPTOMYCIN IN TUBERCULOSIS

KARL H. PFUETZE, M.D.
Cannon Falls, Minnesota
and
MARJORIE M. PYLE, M.D
Rochester, Minnesota

IN PREVIOUS years, the evaluation of chemotherapeutic agents in tuberculosis was most difficult because of the unpredictable natural evolution of this disease. In 1940, Feldman, Hinshaw and Moses found that tuberculous processes in guinea pigs could be suppressed and apparently reversed by treatment with promin. Similar encouraging results were obtained subsequently by these and other investigators by the use of other sulfone compounds in experimental tuberculosis. In later clinical investigations the therapeutic value of the sulfones was suggested but, for a number of reasons, could not be proved. However, since the discovery of streptomycin[9] and the demonstration of the efficacy of this antibiotic against tuberculous infections,[5] sheer weight of evidence has placed the antibacterial treatment of tuberculosis on a firm basis.

Clinical Use

Tuberculous Meningitis.—The specific effect of streptomycin on tuberculous infections was immediately apparent in the ability of the drug to cause remission in tuberculous meningitis and in generalized miliary tuberculosis, conditions almost invariably fatal otherwise. In tuberculous meningitis life is frequently prolonged by the use of streptomycin, remission often is remarkable in degree and in a minority of cases the disease process may prove to be permanently arrested.

Since results are best when treatment is begun early in the course of the disease, the administration of streptomycin should be instituted on presumptive evidence of tuberculous meningitis, without waiting either for bacteriologic confirmation or for development of the classic syndrome. However, treatment should not be withheld if the patient is not seen until the disease is fully developed. One patient at the Mayo Clinic was stuporous and disoriented when treatment with streptomycin was begun, and little improvement was noted until after two months of intensive treatment; yet this patient eventually attained complete remission and remained well two years later.

In a large proportion of the patients whose life is prolonged by chemotherapy, arterial changes develop in the central nervous system, or spinal block or hydrocephalus may occur, owing to the organization of fibrinous exudate. In many cases death has been attributed to these causes. Methods being investigated for the prevention of such disasters include drainage by surgical procedures[10] and the intrathecal injection of heparin.[6]

Disseminated Tuberculosis.—The end results of streptomycin therapy in disseminated tuberculosis are suggested by a review of the first 100 patients treated by the Veterans Administration.[2] One year after the completion of treatment, twenty-four patients were alive, and in fifteen of these patients there was no evidence of active disease. In generalized miliary tuberculosis, the results of streptomycin therapy are almost uniformly good when the drug is administered early in the course of the disease and when meningitis does not develop. The desirability of early diagnosis, when the patient presents a minimum of symptoms, is obvious.

Other Extrapulmonary Tuberculosis.—In most other forms of extrapulmonary tuberculosis the prognosis has been altered or reversed since the advent of chemotherapy. It is now generally agreed that streptomycin is the treatment of choice in tuberculosis of the oropharynx, larynx and tracheobronchial tree; in all cutaneous sinuses and fistulas of tuberculous origin; in tuberculous enteritis and peritonitis, and in tuberculous otitis media. In all of these conditions the proportion of patients who are cured or show marked improvement tends to be in excess of 80 per cent and the proportion of relapses is usually less than 10 per cent.

In a number of other tuberculous conditions streptomycin has not proved to be uniformly effective but a trial of chemotherapy may be indi-

Dr. Pfuetze is Director of Mineral Springs Sanatorium and Dr. Pyle is a Fellow in Medicine, The Mayo Foundation, Rochester, Minnesota.

Read as part of a Symposium on Antibiotics before the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 8, 1948.

cated if no other treatment is available or if the condition has proved refractory to other treatment. Acute tuberculous pericarditis, tuberculous empyema, lupus vulgaris, tuberculous lymphadenitis and, probably, ocular tuberculosis belong in this category.

In tuberculosis of bones and joints, streptomycin has been beneficial in more than half of the cases in which it was used.[1] Probably because the process of healing is slow in this condition, maximal improvement may not be manifest until some time after the completion of chemotherapy. Subsidence of local signs and symptoms may be complete and eventually there may be roentgenographic evidence of healing. In chronic disease, streptomycin is useful in conjunction with surgical treatment, especially when draining sinuses are present.

In genitourinary tuberculosis, streptomycin has brought about some degree of improvement, at least temporarily, in nearly all cases. Alleviation of symptoms is often marked and in approximately three fourths of all cases the urine becomes free of tubercle bacilli during chemotherapy. The bacteriologic conversion is too frequently not permanent and recurrent disease due to streptomycin-resistant bacilli may develop, especially in advanced destructive types of renal tuberculosis. Although there is seldom any change in renal abnormalities as shown by pyelography, lesions of the bladder tend to heal or to improve. Thus streptomycin has been a great boon to patients having bilateral renal tuberculosis, tuberculosis of a solitary kidney and other conditions not amenable to surgical treatment. Genital lesions, as a rule, are not healed by chemotherapy alone. However, in such lesions streptomycin is of value in bringing about the healing of sinuses and as an adjunct to surgical treatment.

Pulmonary Tuberculosis.—In pulmonary tuberculosis, the efficacy of streptomycin depends much more on the type of disease than on its extent. Exudative disease responds best to chemotherapy, proliferative lesions often show some degree of improvement but chronic fibrocaseous disease usually is not materially affected. Therefore, in any series of cases, the results of streptomycin therapy can be correlated closely with the predominant types of lesions. In order that streptomycin may be used to best advantage, careful selection of cases is necessary.

Indications for streptomycin therapy in pulmonary tuberculosis include all acute pneumonic processes, apparently exudative disease which has progressed or remained stationary after an adequate trial of other treatment, recently apparent pulmonary lesions due to hematogenic and bronchiogenic dissemination and tuberculous pleurisy with effusion which is accompanied by toxemia.

Streptomycin has increased the possibilities for collapse therapy and for other surgical treatment of pulmonary tuberculosis. When the disease is in an acute stage, pneumothorax can be initiated sooner and with greater safety when chemotherapy is administered than would be possible otherwise. When exudative lesions are brought under control by means of streptomycin therapy, thoracoplasty and pulmonary resection often become available to patients who were denied surgical treatment previously.

Especially in pulmonary tuberculosis, the permanence of improvement is not a valid test of the efficacy of a chemotherapeutic agent. Whether or not improvement is sustained depends on the patient's own defensive mechanism. If this is inadequate, there is danger of a relapse when chemotherapy is withdrawn or when it becomes ineffective because of the occurrence of bacterial resistance. It is reasonable to suppose that the patient who has demonstrated the need of antibacterial therapy in the first place is more prone to relapse than other patients of similar status regardless of the type of treatment employed. Therefore, it is the physician's responsibility to exercise judgment in the management of each patient, making secure the benefits of chemotherapy by the use of any other therapeutic resource which may be available.

Streptomycin is too valuable to be used wastefully. Until methods are discovered for the prevention of bacterial resistance, the suppressive effect of streptomycin may be available to a patient only once in the course of his tuberculous infection. Therefore, the drug should be reserved for the time when it is really needed. It is not indicated in minimal pulmonary tuberculosis and often should not be used in moderately advanced cases, unless the patient is acutely ill or fails to respond to an adequate trial of other treatment.

Surgical Uses.—Moreover, we do not believe that streptomycin should be used as prophylactic treatment without sufficient reason. Chemothera-

py certainly is not necessary in an uncomplicated thoracoplasty. However, streptomycin probably should be prescribed routinely in pulmonary resection and in other excisional procedures, when there is danger of extension of disease, of reactivation of foci of infection or of hematogenic dissemination. It is generally agreed that chemotherapy is valuable and justifiable in surgical treatment of the genitourinary system, in orthopedic surgery and in the surgical treatment of constrictive pericarditis. When streptomycin is used prophylactically in surgery, the period of preoperative treatment should not be longer than ten to fourteen days in order to insure persistence of the suppressive effect of the drug throughout the postoperative period.

Thus streptomycin is often of great value in conjunction with the surgical treatment of tuberculosis. It is true, likewise, that in some conditions surgical procedures improve the results of chemotherapy. For instance, it has been demonstrated that drainage and possibly débridement of tuberculous abscesses during treatment with streptomycin increases the probability of a successful result.

Bacterial Resistance

The phenomenon of bacterial resistance is one of the chief limiting factors in streptomycin therapy. When streptomycin-sensitive tubercle bacilli are supplanted by drug-resistant organisms, the patient becomes refractory to further chemotherapy. In nearly all instances, resistance of high degree has proved to be a persistent and, possibly, a permanent characteristic of bacterial strains. The virulence of resistant tubercle bacilli apparently is unchanged and especially stringent precautions should be taken to prevent the dissemination of such organisms. Because of the possibility of the production of drug-resistant strains, streptomycin should not be administered without sufficient reason to persons who are expected to remain infectious.

Before exposure to streptomycin, nearly all strains of Mycobacterium tuberculosis, of both human and bovine types, are predominantly sensitive to the drug.[13] After six weeks of treatment, predominantly resistant strains can be recovered from approximately a fourth of all patients who continue to discharge tubercle bacilli; after sixteen weeks of treatment, approximately three fourths of all strains are resistant. It appears, therefore, that it should be possible in many instances to avoid the occurrence of bacterial resistance by curtailment of the duration of treatment. Fortunately, in many tuberculous conditions, treatment for five or six weeks or for even briefer periods often is sufficient to accomplish the purpose of chemotherapy.

When it is possible to make frequent and rapid studies of sensitivity to streptomycin *in vitro,* duration of treatment may be determined on this basis. If cultures of Mycobacterium tuberculosis are made on a solid medium containing various concentrations of streptomycin, it is possible to estimate the relative numbers of sensitive and resistant organisms in any specimen.[7]

Apparently, the number of resistant organisms and the degree of their resistance increase during chemotherapy by a fairly gradual process. Therefore, it may be possible to halt treatment in time to avoid high degrees of resistance. When the growth of cultures recovered from a patient is approximately half as heavy on medium containing 10 micrograms of streptomycin per milliliter as on medium not containing streptomycin, continuation of chemotherapy probably is inadvisable in most cases.

In our experience, egg yolk agar containing 2 per cent glycerin is an easily prepared and otherwise satisfactory medium in which to incorporate streptomycin for the determination of drug sensitivity. The method can be used either for the primary isolation of a culture of Mycobacterium tuberculosis,[7] or for subcultures. Other solid mediums have also been found suitable as a basis for streptomycin-sensitivity studies. The solid medium of Dubos is being used in some laboratories.[8]

Methods being investigated for the prevention or delay of bacterial resistance include regimens of discontinuous treatment and the administration of streptomycin together with other drugs which also are antibacterial in respect to tuberculosis. Preliminary results indicate that some degree of success possibly is achieved by both methods, but the problem of bacterial resistance is by no means solved.

Administration, Dosage and Toxicity

Although streptomycin has been used clinically for more than three years, matters pertaining to dosage and administration are still undergoing critical analysis. It appears that in most types

of tuberculosis an adequate regimen would be one which produces a prolonged bacteriostatic effect but that in the more serious forms of the disease a regimen which is at least partly bactericidal would be highly desirable, if attainable. In tuberculous meningitis, the patient's natural powers of recovery appear to be so insignificant that permanent arrest of the disease process probably occurs only when the infection is eradicated or nearly eradicated.

In practice, results in tuberculous meningitis have been best when treatment with streptomycin was intensive. The consensus at present is that the daily dose of streptomycin should be approximately 0.02 gm. per pound of body weight and that treatment should be continued for at least three or four months. In the experience of most investigators, remission in tuberculous meningitis has been sustained only when intramuscular administration was supplemented by the intrathecal injection of streptomycin, 25 to 100 mg. being administered intrathecally every twenty-four to forty-eight hours during the first six or eight weeks of treatment.

In a report on 105 cases of tuberculous meningitis, the Streptomycin in Tuberculosis Trials Committee of the Medical Research Council of Great Britain[12] stated that a third of the patients receiving streptomycin by both intramuscular and intrathecal routes were doing well after 120 days of observation, whereas only a ninth of the patients receiving the drug by intramuscular administration alone were doing well at the end of that period. In this study it was found that intrathecal injection produced very high concentrations of streptomycin in the cerebrospinal fluid. From one to three hours after the injection of 0.1 gm., the level was 750 to 2,000 micrograms per milliliter of fluid. In such concentrations, streptomycin surely is bactericidal for tubercle bacilli which were accessible to the drug.[4]

In generalized miliary tuberculosis without meningitis, it is probable that the dose of streptomycin should be relatively large and that treatment should be prolonged. It may be true, also, that high concentrations of streptomycin in the blood are necessary in renal tuberculosis, if bacteriologic conversion of the urine is to be permanent. However, in renal tuberculosis, dosage must be adjusted to renal function, because, when function is impaired, concentrations of streptomycin in the blood may be excessive.

In all other forms of tuberculosis which are amenable to chemotherapy, results are satisfactory when the dose of streptomycin is relatively small and when the period of treatment is relatively brief. The pathologic characteristics of most forms of tuberculosis are peculiar in that eradication of the infection probably is seldom possible by any means. Fortunately, the host usually has considerable natural powers of defense, and, when streptomycin is needed to bolster these powers, it appears that clinical results are equally good whether the drug is chiefly bacteriostatic in effect or whether an attempt is made to produce a bactericidal effect.

For two and a half years, at Mineral Springs Sanatorium, we have been using streptomycin in a dose of 1 gm. a day with results comparable to those achieved previously with larger doses. It appears now that further reduction of the dose is possible in the treatment of the more susceptible types of tuberculosis. After a study in which more than 3,000 patients were treated with streptomycin under various systems of dosage, the Streptomycin Committee of the Veterans Administration[11] concluded that there was no detectable loss of therapeutic efficacy as the daily dose was reduced from 2 gm. to 1 gm., and they added, tentatively, that no loss of efficacy appeared to follow a further reduction of the dose to 0.5 gm.

It has been found that the frequency of administration can vary greatly. Results appear to be as good when the drug is administered only once or twice a day as when the total daily dose is divided into a number of fractions administered at frequent intervals. However, as the minimal effective dose is approached, the rationale of infrequent administration becomes questionable.

As the dosage has been reduced, there has been proportionate decrease in the potential toxicity of streptomycin. When the daily dose is 1 gm. or less, toxic manifestations are low in incidence and in degree of severity. Vestibular disturbances occur in only a small proportion of patients receiving small doses of streptomycin; loss of labyrinthine function, when it occurs, tends to be partial and, in some instances apparently reversible.

When dosage is translated into terms of body weight, it should be possible to prescribe streptomycin with the dual assurance of achieving the desired therapeutic result and of avoiding all

toxic effects except those which are due to idiosyncrasy or to acquired sensitization to the drug.

Summary and Conclusions

Streptomycin probably will be the standard of efficacy for the estimation of other chemotherapeutic agents in tuberculosis. It may also be the basis for most new regimens of chemotherapy. The administration of streptomycin together with other compounds which are antibacterial in respect to tuberculosis may have the twofold advantage of an increase in therapeutic effect and of the prevention or delay of the occurrence of bacterial resistance. Until the all-important problem of resistance is solved, it is possible that the phenomenon may be avoided in many instances by arbitrarily limiting the period of treatment to six weeks or less, or by discontinuing treatment whenever studies of sensitivity show a relative increase of the number of resistant tubercle bacilli in cultures recovered from the patient.

The efficacy of streptomycin depends on the accessibility of tuberculous lesions to the drug and on the absence of irreversible anatomic changes. As a rule, these conditions obtain more often in recent lesions than in those of long standing. As chemotherapy becomes established, the ultimate results should improve, because an increasing number of patients will receive streptomycin in stages of disease which are optimal for treatment.

All types of tuberculosis treated with streptomycin are subject to relapse. In pulmonary tuberculosis, especially, streptomycin alone seldom provides definitive treatment. It never was predicted that chemotherapy would supplant rest, collapse therapy and excisional surgery. It has become evident that streptomycin and other therapeutic resources are mutually beneficial and the phthisiologist must now consider chemotherapy in all its aspects in the management of any patient.

AMA PROCURES SEX FILM FOR SCHOOLS

The Committee on Medical Motion Pictures of the AMA has secured the movie, "Human Growth," 16 mm., color, sound, 750 feet (one reel), which is designed to teach the facts of life to children in the sixth through ninth grades of junior high school.

Several months ago *Life* magazine termed this movie, first shown in Oregon, as "epoch-making." It makes clear the growth of the human body, the development of the glands and the reproductive process. But more important, it stimulates classroom discussion.

The movie is only nineteen minutes long, but into it has gone nearly ten years of careful research, financed by the University of Oregon's E. C. Brown Trust Fund. Its author, Dr. Lester F. Beck, a professor of psychology at the university, had tested every step of the filming with parents and teachers.

The committee has procured another film entitled "Human Reproduction," black and white, sound, 825 feet (one reel), showing time twenty-three minutes, which illustrates the anatomy and physiology of the human reproductive system with explanation of ovulation and menstruation.

A third film entitled "A Life In Your Hands," black and white, sound, showing time nine minutes, depicts the new National Blood Program and portrays why this program is so urgent at this time.

Physicians called upon to address lay audiences such as service organizations, parent-teacher associations and other groups may find these films a useful adjunct in their lectures. The films are procurable on loan to physicians from the committee.—Secretary's Letter, A.M.A., Oct. 18, 1948.

STREPTOMYCIN AND NEWER ANTIBIOTICS IN THE TREATMENT OF INFECTIONS OTHER THAN TUBERCULOSIS

WALLACE E. HERRELL, M.D.
Rochester, Minnesota

Streptomycin

CLINICAL experience with the use of streptomycin in the treatment of infections due to organisms sensitive to its action now covers about four years. My discussion on streptomycin is limited to its use in the treatment of infections other than tuberculosis. In this same symposium Dr. Pfuetze has discussed this other aspect of streptomycin therapy.

Some reasonable conclusions concerning the effectiveness as well as the limitations of streptomycin can be made. At this point I should like to mention a matter which cannot be overemphasized, that is, the need for better bacteriologic facilities in all hospitals. If streptomycin or other antibiotics are to be applied intelligently in the treatment of infections and contagious disease, the physician must have the collaboration of his colleagues in the field of bacteriology and he also must familiarize himself with the organisms which are considered sensitive to streptomycin.

Streptomycin has proved exceedingly effective in the treatment of certain types of bacteriemia and infections of the urinary tract due to Gram-negative organisms which are sensitive to its action. The four streptomycin-sensitive organisms which are most commonly encountered in infections of the urinary tract and bacteriemia are Escherichia coli, Pseudomonas aeruginosa, Proteus vulgaris and Aerobacter aerogenes. The results are considerably better in the treatment of infections due to Proteus vulgaris and Aerobacter aerogenes than in the treatment of infections caused by Pseudomonas aeruginosa and Escherichia coli. Organisms belonging to the typhoid-dysentery group are considered fairly sensitive to streptomycin; however, streptomycin has not proved of great value in the treatment of typhoid and dysentery. One of the organisms most sensitive to the action of streptomycin is Klebsiella pneumoniae (Friedländer's bacillus). It is well established that good clinical results have been obtained from use of streptomycin in the treatment of pneumonia and also meningitis due to this organism. Likewise, streptomycin has been found of value in the treatment of ozena and rhinoscleroma, two conditions in which it is not difficult to obtain positive cultures for Klebsiella. Recurrences, however, not infrequently occur because this organism at times appears to possess the ability to become quickly resistant to streptomycin.

Among other organisms which are sensitive to streptomycin are Pasteurella tularensis and Pasteurella pestis, the causes of tularemia and plague. True enough, tularemia is not very common and plague is, of course, rare in this locality. Clinical experience has clearly demonstrated, however, that all forms of tularemia respond magnificently to treatment with adequate doses of streptomycin. By adequate doses for this particular infection I mean 1 to 2 gm. daily for five to seven days. It is unlikely that a causative organism which is resistant to streptomycin will be encountered in tularemia. The literature contains a number of reports suggesting that streptomycin is of great value in the treatment of plague.

It is fortunate that the organisms belonging to the genus Hemophilus are rather sensitive to the action of streptomycin. Hemophilus influenzae, the cause of influenzal meningitis and severe tracheitis, is very sensitive to streptomycin. In the treatment of influenzal meningitis of the severe type, streptomycin should be combined with sulfadiazine and, in some cases, combined also with serum therapy. I am aware that some physicians are reluctant to give streptomycin by the intrathecal route; however, my colleagues and I routinely give 100 mg. in 10 c.c. of physiologic saline solution by this route every other day for the first few days in the treatment of this infection. Hemophilus pertussis, the organism which causes whooping cough, is known to be sensitive to streptomycin; therefore, it is difficult for me to understand why there have been so few clinical reports dealing with the use of streptomycin in the treatment of whooping cough. As I have already said, experimentally it is very effective against this infection. Recently Coffey and Levy reported on the use of streptomycin in four cases of pertussis pneumonia, and Decanio reported on

From the Division of Medicine, Mayo Clinic, Rochester, Minn.
Read as part of a Symposium on Antibiotics at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 8, 1948.

its use in two cases of severe whooping cough. These investigators were of the opinion that streptomycin was effective. I also have used streptomycin in two cases of whooping cough in which it definitely appeared to exert a beneficial effect on the course of the disease. It is my conviction that studies on the use of streptomycin in the treatment of whooping cough should be expanded.

Organisms of the genus Brucella, mainly Brucella abortus, Brucella melitensis and Brucella suis, are only moderately sensitive to streptomycin. The early clinical reports on the use of streptomycin in the treatment of brucellosis indicated that streptomycin had a suppressive effect on this infection, but when used alone for this infection streptomycin could not be considered curative. Pulaski and Amspacher deserve great credit for their observation that streptomycin and sulfadiazine combined seemed to have some additive effect in the treatment of brucellosis. The usual procedure is to give enough sulfadiazine to establish a concentration of 10 to 12 mg. per 100 c.c. of blood and at the same time to administer 2.4 gm. of streptomycin per day by the intramuscular route. This course of treatment is continued for twelve to fourteen days. This method is exceedingly effective in the treatment of the uncomplicated bacteriemic forms of the disease. It is of little or no value in the so-called chronic brucellosis without positive blood cultures. These observations made by Pulaski and Amspacher have been extended considerably by Eisele and McCullough and also by Spink and his colleagues. Results obtained by my colleagues and me are also in agreement with those reported by these investigators.

The use of streptomycin in the treatment of certain infections due to some Gram-positive cocci deserves our attention. On occasions streptomycin has proved itself life saving in the treatment of infections including bacteriemia due to some strains of Staphylococcus aureus and to some strains of streptococci which are, or have become, resistant to penicillin.

From what I have said streptomycin apparently has a wide range of clinical application. On the other hand, let me recapitulate for a moment. The conditions in which streptomycin is effective are infections of the urinary tract and bacteriemia due to sensitive Gram-negative and some Gram-positive microbes. Let me point out, however, that bacteriemia owing to Gram-negative organisms is encountered in relatively few instances in any active medical service. Friedländer's infections also respond satisfactorily to treatment with streptomycin but these infections are certainly not common. Influenzal meningitis and whooping cough are benefited by streptomycin but these infections also are not commonly encountered. Tularemia and plague can be treated satisfactorily and I also might add that cholera may respond satisfactorily to streptomycin therapy. Finally, there is the problem of brucellosis which is, of course, a major one, but streptomycin alone is not entirely effective in the treatment of this infection. In other words, streptomycin is a valuable and useful antibiotic in the treatment of a limited number of infections, some of which are exceedingly rare, at least in Minnesota.

These observations bring to me a question which I would like to lay before you. Who is using all the streptomycin that is being sold? For what is it being used? I am bold enough to suggest that some of our colleagues are treating temperature charts and not the microbes which cause the infection. The fact that streptomycin is not completely without toxic effects should be kept in mind. Prolonged use of streptomycin in amounts of more than 1 gm. per day by any method other than the oral route inevitably will have a toxic effect on the eighth nerve, and a disturbance in vestibular function will result. It is essential, therefore, that more care be exercised in the routine use of this antibiotic.

I should say a word about the oral use of streptomycin. When streptomycin is given by mouth, it does not enter the blood stream and, therefore, it can be given with safety in rather large doses for certain purposes. Two to four grams per day can be given by mouth in four divided doses in the preoperative preparation of patients who are to undergo surgical procedures on the bowel. This is an effective way of reducing the bacterial flora of the intestinal tract. Furthermore, this method is effective in the prevention and the treatment of infections of the urinary tract which on occasion may follow ureteral transplantations to the large bowel.

Methods of administering streptomycin are well established. I will mention a few. It has been our practice to use a stock solution of streptomycin for intramuscular administration. This solu-

tion contains 200 mg. of streptomycin per cubic centimeter of saline solution or distilled water. The average daily dose consists of 1.5 c.c. of this stock solution given every three hours by the intramuscular route. This solution is fairly stable. When streptomycin is to be administered in combination with penicillin, the stock solution contains 100 mg. of streptomycin and 20,000 units of penicillin per cubic centimeter. This solution should be made up fresh every two or three days. For intrathecal administration, it is recommended that 100 mg. of streptomycin be administered in 10 c.c. of saline solution. For inhalation or nebulization therapy, the solutions contain 50 to 100 mg. of streptomycin per cubic centimeter. It is well established that streptomycin may be administered alone or in combination with penicillin. The average daily dose of streptomycin employed for the treatment of severe infections should be 2 to 3 gm. In the treatment of acute infections, it is seldom necessary to employ this amount for longer than ten to fourteen days. In fact, there are some acute infections, such as those of the urinary tract, in which the total duration of treatment probably should not exceed five to seven days. Prolonged periods of treatment with streptomycin are seldom justified except in cases of tuberculosis and some types of brucellosis, particularly those in which the brucellosis is complicated by infection involving the bone or other structures. In this latter situation the same dose schedule which has been recommended for the treatment of tuberculosis is adopted. In other words, the average daily dose is 1 gm. If satisfactory results are to follow the treatment of most acute infections, they will do so within ten to fourteen days of treatment.

Organisms at times will become resistant to streptomycin with incredible rapidity. In addition to the toxic effect on the eighth nerve, cutaneous toxic reactions may occasionally result from streptomycin therapy. These may take the form of either dermatitis or urticaria. Occupational dermatitis often develops among individuals who handle streptomycin, and this is also an important matter.

Streptomycin is, indeed, a useful antibiotic but its usefulness is being seriously hampered by the lack of better selection of cases in which it is to be used. Let me repeat: "Treat the bacteria and not the fever."

Newer Antibiotics

I have been asked to mention some of the newer antibiotics under investigation. The newer antibiotics that I am about to discuss have not been released for general use but they are important enough to justify consideration.

Bacitracin.—Bacitracin is one of the newer antibiotic agents. It was described by Johnson, Anker and Meleney in 1945. It is elaborated by a strain of Bacillus subtilis. Like most antibiotic agents of bacterial origin, it has certain toxic properties. Bacitracin is a rather stable and freely soluble substance. It has a bacterial spectrum not unlike that of penicillin; that is, it is effective against organisms which in general are sensitive to penicillin. For that, among other reasons, it has not been widely used in the treatment of those conditions in which penicillin continues to prove effective. In addition to inhibiting many organisms present in pyogenic infections it appears to be effective against the organisms responsible for so-called gas infections. Like penicillin, it also appears to have some antispirochetal activity. To date, its clinical application[10] has been mainly as a local agent in the treatment of a variety of infections. It can be used in the form of an ointment containing 500 units per gram or as an aqueous solution containing approximately 500 units per cubic centimeter. Eagle and Fleischman have used the material in experimental studies in combination with penicillin in the treatment of syphilis. My colleagues, F. R. Heilman and D. R. Nichols, and I have investigated this agent for some time. We have not felt that the material was sufficiently safe to use it systemically except in a very few instances. Its use is limited because of the nephrotoxic effect which occurs when it is administered to animals as well as to human beings. In human beings albuminuria is practically always seen following its systemic administration. The recommended dose for intramuscular injection is approximately 20,000 units four times per day. If it is to be given by intramuscular injection, great caution should be exercised.

Chloromycetin.—Chloromycetin is an interesting antibiotic which was first described by Ehrlich and his colleagues. This antibiotic is obtained from a strain of Streptomyces; it is a fairly stable, water-soluble substance which can

be administered by the oral route. To date, the most important observation about this substance has to do with its effectiveness against certain rickettsiae.[14] Smadel and his associates[15] have studied this antibiotic rather extensively and have used it clinically in the treatment of murine and scrub typhus. Payne and his colleagues also have reported its use in the treatment of epidemic typhus. According to their observations, the patients begin convalescence within a few days. The recommended dose by mouth is 10 to 15 mg. per kilogram of body weight. The material may be administered by mouth or intravenously, provided it is given slowly. No serious toxic effects have been reported after its use. I have had no experience with this material.

Polymyxin and Aerosporin.—Almost simultaneously these two substances were announced. The first American reports on polymyxin were made by Benedict and Langlykke of the Northern Regional Research Laboratory and by Stansly, Shepherd and White of Johns Hopkins Hospital. This substance is elaborated by Bacillus polymyxa and, therefore, it was given the name "polymyxin." From the early reports it appeared that this substance was effective against some very important Gram-negative microbes including organisms which belong to the colon-typhoid-dysentery group. Rather extensive clinical studies have been made by Schoenbach, Bryer, Bliss and Long at Johns Hopkins Hospital. Polymyxin appears to be a little more toxic than streptomycin but to date no serious difficulties have been encountered except some evidence of renal irritation. My colleagues and I have used polymyxin in the treatment of a few severe infections of the blood stream owing to Gram-negative organisms which were, or had become, resistant to streptomycin. We have been impressed with its effectiveness in some of these cases; however, our clinical studies have not progressed to a point which would justify any final conclusion. At any rate, it appears to be a promising antibiotic.

Aerosporin, which is probably closely related, if not identical, to polymyxin, was reported by the British investigators Ainsworth, Brown and Brownlee. As I have already said, this report appeared almost simultaneously with the report on polymyxin. Aerosporin is elaborated by Bacillus aerosporus and for that reason was called "aerosporin" by the investigators in England. Brownlee and Bushby have studied this substance intensively. Among the important pathogenic organisms against which it is effective are Salmonella typhosa, Hemophilus pertussis and Escherichia coli, as well as many other Gram-negative pathogens. These investigators[3] have pointed out that it was extremely difficult to induce organisms to become resistant to aerosporin. This is an observation of great practical importance. Swift was encouraged by the results obtained from this treatment in 10 cases of whooping cough. This is another interesting substance but it will require further observation before any final statements can be made concerning its clinical use.

Comment

As all realize, I am sure, the antibiotics present an active, ever-broadening subject for study. I would like to re-emphasize, however, that physicians must prepare themselves to use these substances intelligently. This can be accomplished only by closer collaboration of the clinical bacteriologist and the clinical investigator.

SUMMARY OF SYMPOSIUM ON ANTIBIOTICS

WESLEY W. SPINK, M.D.
Minneapolis, Minnesota

YOU have heard three excellent presentations and there is little for me to add except to emphasize one or two points. I should like to stress what Dr. Boyer has had to say concerning the potential toxicity of penicillin. The reactions that this antibiotic induces may be very severe, requiring hospitalization for many days. It is not unusual for the following to happen: an individual with a relatively benign upper respiratory infection is given one or two injections of penicillin, and there ensues a delayed type of reaction simulating serum sickness. While eventual recovery occurs, the patient in the meantime is exceedingly uncomfortable and is incapacitated for many days. While the many advantages of penicillin outweigh the disadvantages of the drug, its virtues should not be abused.

A question of interest to physicians is, with the widespread use of penicillin are not strains of bacteria becoming resistant to the action of the drug? Fortunately, this has not become a serious problem in clinical medicine with the one exception of staphylococcic infections. In several instances highly penicillin-resistant strains of staphylococci have been isolated from tissues or blood of patients at the University Hospitals. In some cases, streptomycin has been used successfully. On the other hand, I do not know of a single instance where a strain of gonococcus has become resistant to penicillin in the patient. This also applies to hemolytic streptococci and pneumococci. One of the outstanding features of penicillin is its failure to induce penicillin-resistant strains of bacteria on a broad scale, such as has occurred with the sulfonamides.

I should like to append a few remarks about the administration of penicillin. Indeed, the man in general practice must be quite confused as a result of the various penicillin products that have reached the market. Much attention today in commercial circles is being focused on penicillin preparations which when injected will be slowly absorbed. High-pressure sales forces are dispatching air mail letters to the medical profession describing the excellence of their new product, which is fitted to yield the maximum results from a single injection of penicillin. As far as we are concerned at the University Hospitals, we have not subscribed to the routine use of any of the products of penicillin which produce delayed absorption. No one has convinced us that sustained and demonstrable levels of penicillin in the blood are necessary in the treatment of bacterial infections. We prefer the use of crystalline penicillin in the form of aqueous solution of the sodium G salt. Furthermore, in the treatment of systemic disease due to many species of bacteria, such as pneumococcic infections and hemolytic streptococcic disease, two or three injections a day of aqueous solutions of penicillin G are given. In the treatment of the average case of lobar pneumonia, 100,000 units every eight to twelve hours are sufficient. In the treatment of subacute bacterial endocarditis and staphylococcic bacteriemia it may be desirable to give larger doses of penicillin at more frequent intervals, that is, every three hours. In the case of relatively resistant strains of streptococcus viridans or staphylococcus, one may administer intravenously 1 million units of crystalline penicillin G in 10 ml. of saline solution. This will produce immediate blood concentrations of over 100 units per ml. Repeated injections of this magnitude may be employed.

There is one additional point that may be made about streptomycin. When this agent is used in the treatment of urinary tract infections it is important to insure an alkaline urine by the administration of alkalies. There appears to be no doubt that the larger the dose the more likely is the clinician to encounter toxic reactions, especially disturbances in vestibular dysfunction. There must be but a rare instance when it becomes necessary to administer more than two grams of streptomycin daily. In using streptomycin in the treatment of brucellosis at the University Hospitals, our policy at present is to give 0.5 gram intramuscularly every eight hours for ten days. At the same time that streptomycin is started, sulfadiazine is administered orally with an initial dose of 3 to 4 grams and then 1 gram every four hours for ten days. Administration of both drugs is discontinued at the end of ten days of treatment.

Again, I should like to express the appreciation for the Association to these men for the excellent presentations that they have made.

THE FIRST LINE OF DEFENSE

LLOYD E. HARRIS, M.D.
Rochester, Minnesota

POINTS 3 and 4 of the National Health Program of the American Medical Association, adopted by the Board of Trustees and the Council on Medical Service, February 14, 1946, projected the broad objectives of the medical profession in the field of maternal and child welfare. These two parts of the program are as follows:

Point No. 3.—The procedures established by modern medicine for advice to the prospective mother and for *adequate care in childbirth* should be made available to all at a price that they can afford to pay. When local funds are lacking for the care of those unable to pay, federal aid should be supplied with funds administered through local or state agencies.

Point No. 4.—The child should have throughout infancy *proper attention, including scientific nutrition, immunization against preventable disease and other services included in infant welfare.* Such services are best supplied by personal contact between the mother and the individual physician but may be provided through child care and infant welfare stations administered under local auspices with support by tax funds whenever the need can be shown.

These objectives are primarily those of the nucleus of an over-all health program. They are concerned with the preventive phase of medicine and public health; "the first line of defense." Prevention of disease is the logical approach to any over-all health program. I should like to emphasize that in speaking of disease and health one should refer, not to physical health alone, but to mental health as well. Mind and body are so closely related and intertwined that to treat them separately, especially in a preventive health program, would be to overlook the whole in focusing on one specific part.

Preventive medicine has been receiving more attention in recent years than it received previously. Not long ago its connotations were more or less limited to purely immunizing procedures for the prevention of some of the communicable diseases. Now more and more it is being recognized that the field is much greater than this one important area. Preventive medicine begins to deal with the individual at the time of conception and theoretically ends with his death from senility. Thus in the over-all health program one can see how the aforementioned points in the National Health Program can be interpreted as a foundation for the whole structure.

"To prevent" is defined usually as "to keep from happening." As just one example of the "to keep from happening" one may cite the problem of premature birth. Prematurity is now the leading cause of death in the first year of life and one of the leading causes for all ages. If by improved prenatal care premature births can be substantially reduced, this approach would seem to be just as important as that of the care of the premature baby after it has arrived. In any kind of a program where all phases are so important, it is difficult to have the vision to place each phase in its position of relative importance. To implement an over-all health program we should not this year stress prenatal care, next year adequate nutrition, the next immunization, and the next mental hygiene, and so forth. On the contrary, we must synchronize all of these phases to the best of our ability into one concerted and continuous effort.

It is quite human to have a rather practical "dollars and cents" viewpoint of things and we are prone to make evaluations in that light. We all would probably desire "value received" for any investment. Many investments made today are in anticipation of "value received" in the future. It would then, to most of us, seem logical to spend $10 today to prevent the expenditure of $100 perhaps next month. That is somewhat of an oversimplification of the purpose of preventive medicine, but from the purely monetary viewpoint would it not seem advisable to spend $1,000 each year to implement an immunization program against smallpox rather than to spend $10,000 for the care of patients who have the disease?

One feels that, if a present-day approach is used, mental disease as well as physical disease may be to some degree preventable. The total cost of the care of mental patients is now a sizable portion of the money expended for medical and hospital services. Is it illogical to assume that an investment in the prevention of mental

Dr. Harris is associated with the Section on Pediatrics, Mayo Clinic, and the Rochester Child Health Institute, Rochester, Minnesota.

Read at the annual meeting of the Minnesota State Medical Association, Minneapolis, Minnesota, June 9, 1948

disease will bring a tenfold return in a reduction of the cost of care of the mentally ill patient?

I should like to consider points 3 and 4 in the National Health Program more in detail and to make some attempt at personal interpretation. What *are* the procedures established by modern medicine for advice to the prospective mother? Today's modern medicine may not be so modern tomorrow. The same must be applied to the term "adequate." It is almost impossible to define "adequate" in relation to a program such as this. The concept of adequacy is ever-changing, as well it should be. What was "adequate" for our grandfathers we would no doubt consider inadequate for ourselves and what we may deem adequate in our day may just as surely be termed totally inadequate by our grandchildren. Adequacy, therefore, may be one of those unobtainable goals by which we progress—always striving toward the goal just beyond our reach.

Advice to the prospective mother may, for the sake of discussion, be divided into physical, mental and nutritional. One is hesitant to make a division even for the sake of discussion for fear of implying a separation and a specificity that are entirely undesirable. The physical advice will include an evaluation of the general health of the mother. Is there any illness or abnormality present that pregnancy will affect in a way harmful to her or the baby? If so, is it amenable to treatment? Most obstetricians feel that this evaluation should be made before *pregnancy* occurs, but *certainly* as soon as it is suspected. After the initial examination it is desirable that the mother be seen regularly throughout the pregnancy. In this way both maternal and infant morbidity and mortality rates may be substantially reduced. The early detection of any of the complications of pregnancy may be life-saving to the mother. Aiding the mother to carry the baby to full term may indeed be life-saving to the baby as well.

The mental and emotional environment of the baby may be well set in this prenatal period. Intelligent, understanding counseling will better prepare the mother to care for her baby. Not a small part of this advice may be devoted to telling her what babies are like and what she may expect in the way of growth and development. A great many tensions and anxieties may be lightened or prevented by some effort to anticipate and interpret, at each stage of development, the baby's normal activities. This is especially true of mothers with their first babies.

Many of us feel now that modern medicine rather shortchanged itself, by improving maternal care to the exclusion of similar thought for the baby. With an ever-increasing number of hospital births occurring, great strides have been made in the reduction of maternal mortality rates. We are realizing, however, that the *emotional* welfare of the newly born baby was rather forgotten. In the desire to maintain him in a relatively sterile atmosphere as far as germs were concerned we made the atmosphere even more sterile in the way of affectionate infant-mother, and even infant-father, relationships. From the mother's point of view the modern hospital situation is usually unsatisfactory because she is constantly anxious about the welfare of her baby, whom she sees only at nursing time. From the infant's standpoint, his desires are not attended to as they arise, because, out of necessity, the organization of the obstetric floor and nursery must be maintained on a rather definite time schedule. If he happens to become hungry at 2:30 when it is visiting time, he is "just plain out of luck."

Poor father! He is definitely looked on as carrying a very special kind of germ. He must view this new heir through a wall of glass, is shooed out of the room when the baby is with the mother, and to consider the possibility of allowing him to *hold* the baby would be revolutionary! Can you see any remote similarity between this situation and a normal family relationship? When babies were born at home these barriers weren't present. There must be a compromise somehow. This compromise is being made on a trial basis in several sections of the country at present. It is commonly known as the "rooming-in" plan and consists simply in having the baby's crib in the mother's room, thus restoring the normal relationship. The baby's needs are attended to as soon as they arise. The mother can see her baby at any minute of the day or night and know that he is all right. She may observe the ordinary techniques of baby care and in a short time take over completely with full confidence. The father is allowed to see his family together and even to hold the baby.

The attitude of the mother toward breast feeding may be determined during the prenatal period and eventually influence not only the baby's well-being but the mother's as well. Breast feeding is "coming back." The incidence of breast feeding will increase undoubtedly as it *again* comes to be the accepted method.

Advice about nutrition during the prenatal period is also being recognized as an extremely important preventive effort. It should have the practical objective of helping the mother to choose the correct diet with due cognizance of the present-day cost of foods, their nutritional value and her *food budget.*

What is adequate care in childbirth? Categorically one would think of adequate care as that which results in the least possible morbidity or mortality rate in either baby or mother. In the majority of confinements the whole process is a purely normal physiologic event and the medical personnel are merely assistants. It is in those situations in which nature needs more than ordinary help that the question of adequate care in childbirth becomes important. Many of these complicating situations may be anticipated if there has been regular prenatal care. Others may be entirely unpredictable and present real emergencies. The problem, then, is first, to have medical personnel trained in the diagnosis and treatment of obstetric problems and emergencies; second, to detect abnormalities early so that the problems may be met *before* they become emergencies—this either in prenatal or in obstetric care; and third, the purely physical need of having the patient and the obstetrician together at the right time. This last point is somewhat of a problem even in the large urban communities and is much more definitely a problem in the rural areas. It has been solved in some regions by having ambulance service available at all times to transport the mothers to hospitals. Thus by bringing the patient to the obstetrician rather than having him make long trips to the patient, he is enabled to give service to more people and is in a position where he has equipment and personnel immediately available for almost any complication that may arise. The alternative, in order to provide even an approximation of good medical care, might be to have available a mobile obstetric unit. However, babies notoriously do not arrive "on schedule" and it would be somewhat disrupting to be delivering Mrs. Jones' baby just at the minute Mrs. Brown's baby was arriving ten miles to the east.

These problems are being worked out and we are certainly going forward rather than backward. One can hardly expect an elaborately appointed and staffed obstetric service to be immediately available in the most remote and sparsely populated parts of our country any more than one would expect elaborate installations in other community enterprises such as fire protection, supermarkets and apartment houses. Neither is elaborate equipment necessary. The well-trained physician in general practice has done, is doing and will continue to do a good job of obstetrics. Getting the patient to the physician rather than the reverse seems a more practical approach in the more remote areas. Real life-saving emergencies are rare and instances in which careful transportation of the patient is contraindicated are still rarer. If the physician has a chance to anticipate difficulty in prenatal visits he may make arrangements beforehand for consultation or delivery in a larger center where facilities are available to handle the problem.

Now let us assume that point 3, relative to the mothers, has been carried out to the best ability of all concerned and that we have a brand-new member of the community on our hands.

Point 4, care of the baby, now comes into sharper focus. There should be no definite demarcation between obstetric and pediatric care, but a real continuity of service. It is much like a relay race in which for a very short time the obstetric and pediatric practitioners are both carrying the baton. However, in by far the majority of instances it is the physician in general practice who is running the whole race and plays the role of a steady distance runner rather than of the sprinter.

I should like to comment briefly on the statement made in point 4 that "such services," referring to preventive pediatric care, "are best supplied by personal contact between the mother and the individual physician." This element of personal contact, personal interest and mutual confidence is that indefinable something for which there can be no complete substitute. Although the usual large well-baby conferences or clinics may approximate the relationship and provide excellent service, the rapport between mother, baby and physician is not quite the same.

In Rochester we conduct ten well-baby clinics a week in the city and several out in the smaller communities of Olmsted County each month. These clinics are staffed by pediatric Fellows of the Mayo Foundation and consultants from the Section on Pediatrics of the Mayo Clinic and from the Rochester Child Health Institute. The methods, general philosophy of growth, and devel-

opment and infant care are uniform. We are attempting to provide a comprehensive preventive medical program for all the children of the community. One of our greatest problems is to achieve a continuity of personal contact between the mothers and the physicians. The Fellow's period of service in the clinics is only three months. He and the patient are just beginning to know each other when another physician comes on the service. The consultants, however, play a supervisory role and are present or available at each clinic. The same consultants have supervised the care of the baby in the hospital during the newborn period and have talked with the mother each day at that time. In this way we hope to give some continuity of care and personal contact, but we feel that it falls short of the situation in which the parents have personally chosen the physician and this bond continues throughout infancy, childhood and the rest of life. An automobile is rather an impersonal thing; yet how many of us have a favorite garage and mechanic to whom we go when in car trouble? Another mechanic may do the work every bit as well but if we don't know him we lack confidence in the job done. When one realizes how prominent the element of personal confidence is even with such inanimate things as automobiles and groceries it is understandable that this relationship is infinitely more important in child care. Are not our children our greatest and most important possessions and responsibilities?

I shall therefore assume that the most desirable situation would be that in which the preventive program is carried out by the private physician. When this situation is not obtainable, then the child care and infant welfare stations will be a substitute and should be as complete a substitute as possible.

To define or interpret what may be "proper attention throughout infancy" is again surprisingly difficult. Minimal standards can be only approximations and maximal or ideal standards are unknown. Two years ago the American Academy of Pediatrics, with the assistance of the Children's Bureau and the United States Public Health Service, initiated a study of child health services throughout the United States. This includes, as well, an attempt to evaluate pediatric education in medical schools and hospitals. The analysis of these data together with recommendations will be published sometime this year. It is anticipated that this study will give a comprehensive and fairly accurate picture of the present status of child health services and enable communities, especially on a state level, to improve their local services. It will provide a factual basis for future planning. It is becoming more evident and perfectly logical that, before the problem of distribution of child care can be effectively met, more emphasis on pediatric education must be made in medical schools and subsequent intern and postgraduate programs. Improvement of rural health facilities, however, need not wait on the development of a long-term educational program but may proceed simultaneously as part of the training program.

There are some phases of infant care that are felt to be basic and can serve as a foundation for the phrase "proper care." Nutritional advice was one of the first reasons for pediatrics to come into existence as a specialty. Advances in infant feeding in the past fifty years have been tremendous and have resulted in great simplification of the problem. As knowledge has increased, mortality rates from nutritional disturbances have decreased. Infantile diarrhea or "cholera morbus" is now insignificant in comparison to the problem it was a generation ago. The vitamin deficiencies such as rickets and scurvy are almost medical curiosities today. Nutritional advice should not stop after the "formula" period but should continue throughout childhood and on to adult life.

Immunization against preventable disease has most certainly been proved to be effective. The skepticism and superstition of the public concerning these procedures are becoming less evident. There are still some parents who say: "I wasn't vaccinated and I didn't get smallpox, so why should my baby be vaccinated?" They were indeed fortunate that they did not get smallpox but are they justified in taking the gamble for their child? Unfortunately, the baby or child has no choice in the decision. It is entirely the parents' responsibility. If a child seriously ill with diphtheria could say, "Mommy and Daddy, why didn't I get shots like Bobby did?" what could their answer be if they had assumed the responsibility of neglecting to have the immunizations done? At the present time effective protection can be offered against smallpox, diphtheria, whooping cough and tetanus. In some communities and under certain conditions scarlet fever, typhoid,

typhus, yellow fever, tuberculosis and cholera immunizations may be indicated. Universal immunization programs should be the concern and responsibility of all of us in the medical and allied professions. When smallpox and diphtheria are present in our community or state, we should each one of us feel that neglect of universal immunization is a *personal* failure and should do something about it.

The phrase "and other services included in infant welfare" could be interpreted to cover almost anything. However, I should like to feel that it applies primarily to the service of interpreting the infant's needs and behavior to the parents and of helping them appreciate what is normal growth and development. This service has been termed "mental hygiene." Since "mental hygiene" has somewhat the suggestion of abnormality, the title "child guidance," though not entirely satisfactory, seems more appropriate. Pediatric education, in its realization that there is not only a "sick child" to be considered but also a "well child," is putting more emphasis on the teaching of what a normal child is like. If parental guidance for a child can be adjusted to his normal capabilities and growth trends, his attainment of acceptable social behavior or conformity will be smoother. He will develop greater emotional stability if demands are made consistent with his abilities.

It is the nature of human life to be beset by daily crises of some degree. It certainly seems to be true in our world of today. One may assume that it will be not too different in the world of tomorrow. The patterns may change, but basically the problems of food, shelter and getting along with our neighbors will probably be similar. Therefore if, by child guidance, one can establish a smooth development, an understanding between child and parent and a chance for individual potentialities to develop, the frustrations of adult life may be less jolting. This guidance may be achieved through the individual practitioner, through the pediatrician, the public health nurse, the teacher, the social worker or others especially interested and trained in child care. The more deviate problems may require the services of a psychologist or psychiatrist. All of us, including the psychologist and psychiatrist, must first have a basic understanding of the normal.

Therefore, advice to the prospective mother, adequate care in childbirth and proper attention for the child throughout infancy are the objectives of the National Health Program of the American Medical Association. To bring a healthy child into the world and then to keep him healthy in mind and body would certainly seem to be "the first line of defense."

RESEARCH COUNCIL FOR ECONOMIC SECURITY

Voluntary plan for protection against sickness, old age, premature death and other major hazards now cover hundreds of thousands of workers in the Chicago metropolitan area. This was revealed in a recent study, *"Employe Benefit Plans in Chicago,"* just released by the Research Council for Economic Security, Chicago.

Questionnaires were sent to more than 2,000 employers, both large and small. Of these, 35 per cent were returned, reporting on about 700,000 employes. Of this number, 85 per cent have life insurance and about the same number hospital insurance. These are followed by compensation for wage loss due to illness (69 per cent of employes in reporting firms); pension and retirement plans (68 per cent); surgical benefits (50 per cent); and prepaid medical care (6 per cent). These figures apply only to employes in firms which participated. For the entire labor force, the figures would be somewhat lower. Protection by government systems and by individual employes themselves are not included.

"The purpose of the survey," said Gerhard Hirschfeld, Director of the Council, "is to show as accurately as possible how much protection industry provides for its employes on a voluntary basis. Similar surveys, now under way in St. Louis, Cleveland, Pittsburgh, Minneapolis, Saint Paul and other major cities, are expected to throw more light upon the nature and extent of employe benefit plans throughout the country."

The Research Council is a non-profit, non-partisan, privately financed organization engaged in studies in the field of social and economic security. Its chairman is Bertram J. Cahn, President of B. Kuppenheimer & Co.

THE TREATMENT OF OPEN WOUNDS OF THE HAND

MICHAEL L. MASON, M.D., F.A.C.S.

Chicago, Illinois

(Continued from November issue.)

Closure of the Wound

The ideal termination of the operation is closure of the wound. Primary closure by some means or other can be accomplished in practically all wounds which have been seen within eight hours of their occurrence.

If suture can be done, it should be accomplished without tension on the skin edges or on any tissue. Tight sutures cause necrosis with resultant tissue autolysis, and what is worse, furnish ready food for the ubiquitous facultative bacteria which thrive on dead tissue.

If closure by suture is impossible, the wound should be closed with some type of skin graft, either a free graft or a pedicle flap. In most cases, a thick split graft is the best choice. It will take very well on fresh wound surfaces and will very often serve as definitive closure. It may be removed in any size required. Very small grafts may be removed from volar surface of the forearm with an ordinary scalpel or razor blade. Larger split grafts will have to come from some other surface, usually the thigh. A dermatome is not necessary, since often the grafts are not large and a good sharp skin graft knife will serve very well and takes less time. The free full-thickness graft is seldom used on the surface of a fresh traumatic wound, since it requires almost perfect conditions for a successful take.

In some instances where there is exposure of bone or tendon, the surgeon may slide a flap of skin from one side of the wound and cover the flap bed with a split graft.

In most cases where bones, joints and tendons are exposed, they must be covered with a pedunculated flap. While the need for an immediate pedicled flap does not often arise, where it is indicated it is of immense value and will save bones and tendons from necrosis, which is certain to follow if they are left bare. Thus, in the degloving injuries, placing the hand at once under an abdominal flap will save the hand, whereas leaving bones and tendons exposed is sure to end in extensive and often irreparable loss. Flaps, however, need not always be large; some very small defects are often best covered with a small flap. For example, the tips of fingers where bone is exposed are best covered with a tiny pedicled flap raised from the opposite chest wall.

The surgeon should learn to take advantage of any adventitious flaps which may present themselves. Thus, the destruction of a finger may leave a sizable flap of skin which may be utilized to close defects of the palm or dorsum.

Secondary Closure

Secondary closure, as was developed during the recent war, should be generally recognized as a method of early closure, almost as satisfactory as primary closure except that primary nerve and tendon suture are not permissible. Wounds which are seen too late for primary closure or which are probably not surgically clean even after careful cleansing, or which for some reason or other cannot be kept under proper surveillance, will have to be left open. Such wounds receive the same initial care as any other wound. Joint capsules are closed if they have been opened, but nerves and tendons are not sutured. The wound surface is covered with a layer of fine mesh gauze and over this is placed a pressure dressing. A splint is applied and the wound left alone unless some untoward symptom arises. At the end of four to six days, the wound is uncovered in the operating room, and if it "looks all right" a closure is accomplished at this time.

Fractured bones may also be reduced often by internal fixation at this time, but it has never seemed logical to perform nerve and tendon repair, largely because of the dissection required to expose the ends and because they would lie in scar tissue. Secondary nerve and tendon repair is performed later after the wound has healed and the tissues have softened up.

The whole success of secondary closure depends upon the care with which the primary cleansing and excision of the wound has been carried out.

If this care has been inadequate, the wound at time of inspection will be found to contain necrotic tissue and often to evidence invasive infection. In such cases, further cleansing and debridement must be done and closure attempted several days later with, however, much less chance of success.

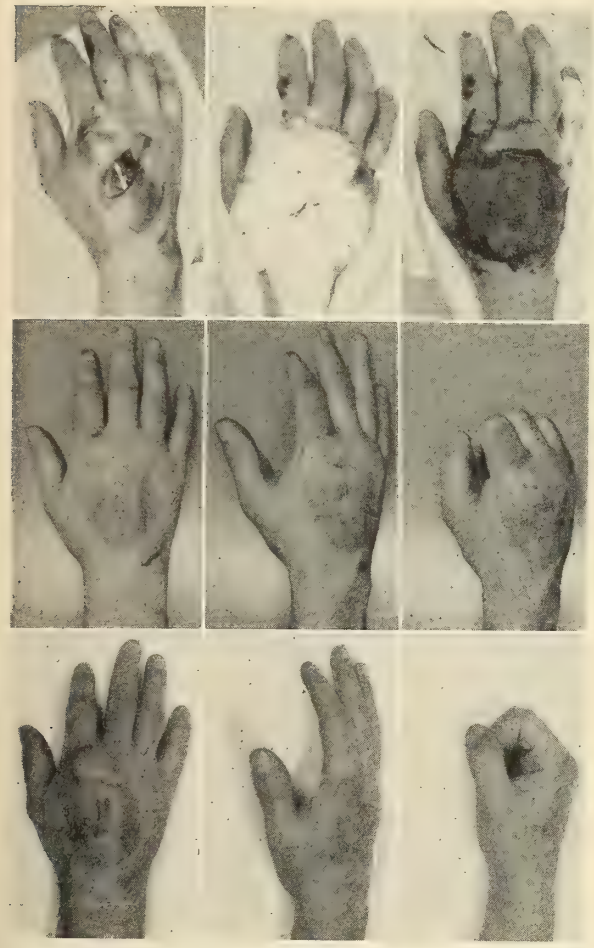

Fig. 3. Crushing burn sustained when hand was caught between a cold roller below, a hot roller above. Some skin actually burned away, remaining skin over large area of dorsum completely devitalized by pressure and third degree burn. Common extensor tendons to index and middle fingers destroyed and ends charred. Immediate excision, two and a-half hours after injury, of all devitalized tissue. Stumps of tendons were sutured to adjacent tendons and a large split graft applied. Upper row shows hand on admission and at time of first dressing six days later. Center row shows hand two months after injury, and lower row, three months after injury.

The Compression Dressing

The use of compression in surgery is a principle of treatment which has been recognized for many years. We owe to Blair and to Koch the present widespread use of it in wound surgery. During the past decade, experimental evidence has been furnished of the value of compression in such conditions as crushing injuries, burns, and other traumas.

The arguments upon which a compression dressing is used are briefly that tissues are ordinarily under a certain physiologic pressure. This pressure counter-balances the pressure of blood in the vessels, supports the arteries and veins going to and coming from a part, and maintains proper relationship between the intra- and extravascular fluids. When these pressure relationships are disturbed following trauma, fluid exchanges within the tissues are out of balance, and swelling occurs. The veins, without their customary external pressure, may dilate and the blood stagnate within them.

In the wounds of the hand this loss of fluid into the tissues leaves in its wake a hard swelling, which takes weeks or months to absorb and results in an extensive disabling fibrosis. Therefore, to prevent this swelling, the re-establishment of the proper pressure relationship is indicated as soon as possible following injury.

The support of the venous return by means of a compression dressing is another important function of the compression dressing. Many times we see a skin flap which has undergone necrosis, not because of the lack of arterial blood supply but because of the venous congestion which occurs.

The plastic surgeons have long emphasized the need for compression on skin flaps, not only to prevent swelling, but also to support the veins. Flaps which ordinarily should live may very well die if this support is lacking.

Dead spaces caused by tissue disruption, under avulsed flaps, et cetera, can be obliterated by a properly adjusted compression dressing. These spaces become filled with blood or serum which may take weeks to absorb and form excellent pabulum for bacterial growth.

Torn and injured tissues and tissues after operation tend to ooze blood and serum into the wound. This oozing may be controlled by properly applied compression. Severe arterial hemorrhage, on the other hand, will not be controlled by a pressure dressing unless it is applied too tightly.

If correctly applied, a compression dressing is soothing and relieves pain. This is partly due to

control of swelling and partly due to the immobilization which compression produces.

I can mention but a few of the conditions in which the compression dressing has proved to be a valuable adjunct to surgery of the hand. In many of these conditions it will make the difference between success and failure. After all operations on the hand, a compression dressing should be applied before the blood pressure cuff has been released. In this way, not only will the postoperative swelling be minimized but the oozing which will occur after operation will be largely controlled. As first aid for injuries of the hand, the dressing should be voluminous and compressive from the start so as to prevent the swelling which will occur between the time the wound is incurred and the time the patient receives definitive care. Closed injuries such as sprains and simple fractures which do not require operative intervention should be dressed in compression from the start, for the reasons noted above. Burns of the hand are best treated by splinting and a compression dressing. Flaps and free skin grafts are dressed with compression dressings. Granulating wounds such as occur after burns or other injuries respond to this treatment, often cleaning up these areas quite rapidly.

Fig. 4. Secondary closure of degloving injury and traumatic amputation. Patient was received for care six days after injury; the wound was clean and granulating and was immediately covered with a split graft. Later, as shown in the lower row, this thin graft was excised and a pedunculated flap placed over the dorsum.

Careful instruction is always needed when an intern is told to apply a compression dressing. Even after observing its application time after time, the new resident seldom applies a compression dressing correctly until he has had several weeks' experience. The dressing must be voluminous and made up of many layers of fluffed-up gauze or mechanics' waste, evenly applied over the entire part. Whatever the material used, it should be soft, elastic and absorbent. It must apply a uniform resilient pressure distributed evenly over the whole area to be compressed and must produce no constriction. It must be firm but not tight. It should cover the whole hand and lower forearm in case of most injuries of the hand, while if the lower forearm is involved, the dressing should go to the elbow or beyond. In applying the dressing to the hand the fingers must be separated by the gauze so that they are not compressed against each other and so that sweaty secretions will not accumulate between them. If a splint is incorporated in the dressings, as it usually is, it must be well padded to prevent the development of pressure areas. It is difficult to tell anyone how snug to make this dressing; one learns from experience. If large amounts of dressings are used, it is difficult to get it too

tight, but it is possible, especially if an elastic bandage containing rubber strands is wound on at full stretch.

Immobilization

In this day of early ambulation and emphasis on early resumption of function, the surgeon is apt to forget that injured tissues require rest. While it is true that following abdominal surgery the patient can frequently be allowed out of bed a few days after even the most serious operation, the surgeon who neglects proper splinting for injuries of the hand is courting disaster. There is probably no surer way of causing breakdown of incisions, rupture of sutured tendons and post-operative infections following surgery of the hand than to neglect to splint the hand afterwards for a sufficiently long period of time to permit the tissues to heal.

In what position should it be splinted; how much of the hand should be splinted; and how long should immobilization be maintained?

The position in which the hand should be splinted depends on the nature of the operation performed and the conditions present. In general, the ideal position in which to splint the hand is the *position of function.* This is the grasping position, in which the wrist is dorsiflexed about 45 degrees, the fingers flexed about 30 degrees at all joints and slightly seperated from each other. The thumb is swung around into a position of abduction and rotation so that its pad faces but does not touch the pads of the fingers. In this position even the slightest motion is sufficient to permit some function, and if the hand should become stiff, is the most useful position. Also, from this position the physical therapist or the patient can most readily restore use. In this position the collateral ligaments of the metacarpo-phalangeal joints and interphalangeal joints are stretched their longest and do not shorten and produce contractures.

The position of function should be used in every case of hand injury except those in which repair of tendons or nerves require relaxation in some other position. The position of function is an excellent one in which to immobilize fractures of the hand. Practically all fractures of the hand can be reduced and held in proper reduction by molding them into reduction over the proper splint and holding them there in the position of function with pressure dressings. Only in very rare instances does it seem indicated to use traction for this purpose. The possibility of reducing fractures of the hand on a firm splint makes it possible to apply a compressive dressing to prevent the post-injury edema and swelling which makes for so much disability.

Sutured flexor tendons must be splinted in relaxation with the wrist and fingers in flexion. Most of the relaxation should be taken up by flexion of the wrist, which may be brought up to 45 degrees. The fingers should not be so acutely flexed. The metacarpo-phalangeal joints should not be flexed beyond 30 degrees. Sutured extensor tendons should be splinted in extension, but here we must extend completely all the affected joints, otherwise, we will end up with tendons too long for proper function.

Muscles paralyzed by division of the motor nerves, should be splinted in relaxation so that the unopposed antagonists will not stretch and damage them. We are familiar with the proper splinting for radial nerve paralysis, but we forget that the small muscles of the hand may be paralyzed and they must also be protected by splinting. Thus, the interossei and lumbricales are protected by a splint which holds the metacarpo-phalangeal joints in slight flexion and holds the thumb in slight adduction. Where the median nerve is divided, the small muscles of the thenar eminence are prevented from stretching by holding the thumb in the grasping position, i.e., rotated and adducted around to face the finger pads.

The application of the splint should become as automatic at the end of the operation as the application of the dressing and should be kept in mind at all times when treating hand wounds and infections.

The length of time that the splint should be kept on will vary somewhat with the condition present. Roughly speaking, the hand should be kept splinted until the tissues have healed sufficiently strong to take over their function without support. While there is no doubt that splinting can be kept up longer than necessary, with resultant stiff joints, it is my feeling that in most cases stiff joints are due to inflammatory exudate and not to splinting *per se.* The usual hand injury without nerve, tendon or bone damage, which heals by primary intention requires splinting for but seven to ten days. Fractures of the hand are usually well enough consolidated in two weeks to permit removal of the splint once daily to allow

the patient to soak the hand in warm, soapy water and begin mobilization. After three or, at most, four weeks, the splint may be discarded.

Divided flexor tendons should be kept splinted without motion for three weeks, following which the splint is gradually straightened out over a period of from one to two weeks, during which time the patient may begin active use within the limits permitted by the splinting. In case of the extensor tendons, the splinting must be kept up about five weeks, since these tendons are more likely to be stretched by the more powerful flexors. Also, in case of the extensors, it is sometimes wise, after daily splinting has been discontinued, to have the patient wear the splint at night for several weeks, since the hand is normally held in flexion during sleep.

Paralyzed muscles should be kept relaxed as long as their nerve supply is lacking, or until some substitution has been provided for the muscle. This may mean wearing a splint for many months in case of the ulnar or median nerves. In these cases, the splints should be such as to permit the patient to carry on his usual activities and still wear the splint.

Follow-Up and After-Care

Fully as important as the initial surgery in case of injuries of the hand is the follow-up care of these patients. Failure to obtain satisfactory results after good surgical treatment is often due to errors in the postoperative management. Failure to maintain immobilization for a sufficiently long period of time accounts for many instances of wound breakdown or tendon rupture after repair.

The initial dressings are seldom changed before the fifth to seventh day, at which time it is well to discontinue the pressure dressing. At this time the suture line is inspected, and if any of the sutures seem to be too tight, they may be snipped. By the seventh to tenth day the sutures may be removed, after which the dressings are changed every second or third day so that sweaty secretions do not accumulate. In case of simple injuries the dressings may be left off entirely at the end of ten days and the patient instructed to soak his hand once daily for fifteen to twenty minutes to limber up the joints. In simple injuries a few days of daily soaking are enough to restore function to normal. In case of tendon repair, the patient must have the hand immobilized for a longer period of time, and the early soakings must be given the hand by the surgeon or his assistant. Only after the end of three weeks is it entirely safe for the patient to start his own daily soakings. The daily soak, a regular institution with us, is not a simple perfunctory washing of the hand, but requires about fifteen minutes of gentle washing in soapy water. The surgeon gives the first few soakings so that the patient "gets the idea" and learns how much he can do. Thereafter, he does this washing himself and is encouraged to massage the hand gently with the warm soapy water and a wash rag. This combination of heat and massage does wonders in mobilizing the hand and in restoring function.

At the end of three weeks following flexor tendon repair, the splint is straightened out somewhat and the patient is allowed to flex the fingers actively, but extension is limited by the splint. This straightened splint he wears for a week or ten days, at which time it is removed entirely, and his further care depends on the rapidity with which he regains function. In a good percentage of cases no formal physical therapy is required, only the daily soakings and the daily use to which the hand is put. If the patient's job is not too strenuous, he is encouraged to go back to work at the end of the fifth or sixth week. If no suitable work can be found for him, he is instructed to do odd jobs around the house, and we have found that dishwashing is a very valuable therapeutic adjunct.

Where skin grafts have been applied, dressings are done on the fifth or sixth day, at which time the silk overties are cut and the pressure roll is removed. Sutures about the graft are also removed, and the pressure and splint are again applied. Dressings are performed every second day and the pressure maintained for a total of fourteen to twenty days. When the grafted area is first completely exposed, the patient is cautioned against injuring the graft, often wearing a protective glove or mitten for awhile. The graft is sensitive to heat and sunlight, to which exposure should be very gradual.

Fractured phalanges and metacarpals may usually be dressed at the end of two weeks, and if other wounds permit, a light protective splint may be applied, which the patient can remove daily for washing. At the end of three weeks, it is usually possible to remove the splint entirely,

but the patient should wear the splint at night for another two weeks.

Operative Technique

A few details of operative technique are of importance. It is not possible to discuss them all, but they deserve mention since so much depends on a careful technique if the surgeon expects to obtain good results in surgery of the hand.

General anesthesia is practically always best for operations on the hand, since the surgeon does not feel so hurried and can work slowly and carefully. The blood pressure cuff which is applied to produce a bloodless field is very uncomfortable for the patient after the first few minutes under local anesthesia. Also, the need for enlarging incisions and wider exposure than may have seemed to be necessary at the start militate against the use of a local anesthetic.

A bloodless field is an essential to a careful operation. Without it the surgeon is seriously handicapped in locating the injured structures and in repairing them when found. The constant sponging that must be done when the field constantly floods with blood is not only time-consuming but traumatizing to the tissues. A bloodless field is best secured with a blood pressure apparatus applied to the arm loosely and covered with a bandage to prevent it from "popping out" when inflated. The arm is held up for a minute to allow the blood to run out of it, and the cuff is then rapidly inflated to 280 mm. Hg. It is kept up to this pressure until the surgeon has completed his cleasing and the excision of the devitalized tissue, and has identified and mobilized the structures requiring repair. The cuff is then deflated, and the wound is covered with a warm moist "lap" pad during the first few minutes of the reactive hyperemia which follows its release. The wound is then inspected, and all bleeders are caught and ligated with fine silk. The arm is again elevated, the cuff inflated, the operation completed and the compression dressing applied before it is finally released. We have never seen any trouble come from this technique, even though the cuff may be on for as long as two hours during the dissection and for well over two hours during repair and until the final dressing is applied. Higher pressures than that mentioned may well cause trouble, and the use of ordinary rubber tourniquets or pneumatic cuffs which produce very high pressures may lead to trouble.

Adequate exposure of the injured structures is necessary and is seldom provided by the wound itself. This is especially true in case of divided tendons which retract well up or down in the tissues and cannot be located through the exposure offered by the wound. To "fish" for tendons with forceps is poor technique, often unsuccessful, and even if the tendons are found, seldom is there enough space in the wound to permit a neat suture. Enlarging incisions are therefore usually required to afford adequate exposure with a minimum of retraction. The enlargement of wound must be done with some consideration. Too often a transverse wound across the wrist or finger is enlarged by a longitudinal incision straight across the center of the wound, producing a cruciate defect which may give good exposure but leaves a badly disabling scar. The nerves and tendons lie directly under this scar for its whole course and are certain to become adherent to it. The four corners of the scar are likely to become necrotic. Later on, as the scar contracts, it produces a flexion contracture of varying severity. If the result of the initial surgery is not successful, the surgeon who undertakes the secondary repair will find himself very much handicapped. The correct lateral incision may be impossible, and to correct the midline scar may entail the application of a pedicled flap. Enlarging incisions follow the same principles which govern elective incisions. The midline of fingers, wrist and forearm should be avoided because of the certainty of contracting scars. Longitudinal incisions on the fingers and forearm should be made along the sides, and if the volar surface is to be crossed, it should be crossed transversely. In the palm the transverse incision is also best, but incisions may follow the longitudinal creases at the borders of the thenar and hypothenar eminences. Incisions should follow as nearly as possible the natural folds of the skin, not necessarily in the creases, but parallel to them. The incisions should be planned so as to produce flaps of skin with subcutaneous tissue under them so that repaired structures lie against subcutaneous fat. When the incisions are deepened, care must be exercised in dividing the pulleys. Only when necessary should the retaining ligaments be divided, otherwise bowing may occur. If it has

been necessary to divide the pulleys, they should be repaired.

Gentleness in handling tissues has been stressed for many years, not only in surgery of the hand but in all surgery. In surgery of the hand, gentleness is an absolute necessity if the surgeon is to attain any sort of results at all. Not only must primary healing of the skin be secured, but the tissues beneath must be soft and without adhesions if function is to result. The tendons must not be handled roughly, squeezed with forceps or with rough gauze. Rough, forceful retraction may traumatize the edges of the wound so as to produce areas of necrosis of the skin and subsequent disturbance in healing and often deeper infection. For the same reason, the introduction into the wound of irritant chemicals is to be avoided, since they are almost certain to lead to exudate and scar.

Exact hemostasis must be secured. As vessels are encountered during dissection, they are caught in forceps and lighted with fine silk. At the time of the first deflation of the blood pressure cuff, the bleeding points not seen during the dissection are picked up and ligated. At the close of the operation the compression dressing is applied before the cuff is finally deflated so that the oozing which would occur from the freshly divided surfaces is controlled by pressure.

Fine sutures and ligatures are used so as to leave as little foreign material in the wound as possible at the close. We prefer the use of silk since it is very strong for its size and is very slightly irritant. Cotton and steel wire are also excellent for use in the hand. The main point is that sutures be as small as possible and still accomplish the job.

Secondary Repair

The matter of secondary repair of divided nerves and tendons of the hand cannot be gone into at this time. This, however, can be said: The surgeon who treats an acute injury of the hand in which he does not believe nerves and tendons should be repaired primarily should remember that secondary repairs are almost as good as primary repairs if the initial wound has healed by primary intention, or even if an early secondary closure was performed. He should not hesitate to omit nerve and tendon suture if the situation is not ideal.

PROPYLTHIOURACIL

(6-propyl-2-thiouracil.—$C_7H_{10}N_2OS$.—M. W. 170.226)

Actions and Uses.—Propylthiouracil interferes with the formation of thyroxin by the thyroid gland. It is useful in the treatment of hyperthyroidism, thyrotoxicosis and thyroiditis. It is of no value and should not be used in other derangements of thyroid activity or in conditions not associated with hyperthyroidism.

Since propylthiouracil does not inactivate or interfere with the action of thyroxin already formed and stored in the gland, the effects of propylthiouracil medication do not appear until this store of thyroxin has been utilized. It may take several days to several weeks for the signs of decreased thyroid activity to become manifest, particularly if the patient has received previous iodine therapy.

Not all patients experience a permanent remission following propylthiouracil therapy, and the duration of treatment necessary to secure permanent relief from hyperthyroidism has not been determined. On the basis of the available information, it can be recommended only that propylthiouracil be used for preoperative treatment or for those patients for whom operation is contraindicated. The wisdom of depending on propylthiouracil as a substitute for operative procedure can be determined only by following the results of investigations carried on for longer periods.

Propylthiouracil is capable of producing adverse reactions in some patients. The incidence and severity of these reactions are unpredictable, but they occur with less frequency than do those following medication with the parent compound, thiouracil. The severest complication of propylthiouracil therapy is granulocytopenia. Less severe reactions may include leukopenia, drug fever and dermatitis. The drug should be discontinued and appropriate therapy commenced immediately on the detection of signs of any of these complications.

Since the mild and the juvenile types of hyperthyroidism can frequently be controlled adequately by iodine therapy alone, propylthiouracil should not be used for these patients unless the safer form of therapy proves ineffective.

Dosage.—For severe cases of hyperthyroidism, initial doses of 50 mg. of propylthiouracil every eight hours appear to be effective in routine treatment, and 50 mg. twice daily in milder cases. Iodine should be administered for two or three weeks immediately before thyroidectomy.

The effective dosage of propylthiouracil should be continued until all signs and symptoms of the disease have been brought under control. Adequate maintenance dosage may best be established by determinations of the basal metabolic rate. *Patients should be instructed to cease medication and report to their physician immediately if any adverse symptoms such as sore throat, fever, coryza or malaise are experienced.*—New and Non-Official Remedies, J.A.M.A., 138:429 (Oct. 9) 1948.

CHRONIC SCHISTOSOMIASIS JAPONICA DIAGNOSED BY RECTAL BIOPSY

Report of Case

L. ZIEVE, M.D., and R. H. CONLEY, M.D.
Minneapolis, Minnesota

PRACTICALLY all of the cases of schistosomiasis in the armed forces during the last war were acquired on the Philippine Island of Leyte during late 1944. Approximately 1,500 cases were treated while in the service, and it is estimated that an equivalent number, less severely infected on the average, went undiagnosed.[7] The latter would be expected to present the most difficult diagnostic problems, particularly when presence of ova in the stools is used as the criterion. There probably have been few new cases diagnosed in veterans to date. The present case is the first one seen at the Minneapolis Veterans Hospital. It illustrates the need for alertness to the possibility of schistosomiasis in a veteran who has been on Leyte. It also illustrates the difficulties inherent in the detection of the early chronic form of schistosomiasis japonica and demonstrates a useful technique for diagnosis.

Case Report

First Admission.—R. R., a twenty-nine-year-old white male farmer, was admitted to the hospital for the first time on September 30, 1947, complaining of recurrent diarrhea and right upper quadrant abdominal pain.

His first episodes of diarrhea occurred in November, 1944, following three weeks of frequent exposure in rice paddies, streams, and ditches on Leyte. He had high fever and severe diarrhea for eight days and was treated nonspecifically with temporary relief of his symptoms. However, he continued to have intermittent diarrhea once or twice weekly and was eventually hospitalized in a station hospital on Okinawa for forty-four days (Aug. 12 to Sept. 25, 1945). During this hospitalization he had eosinophilia up to 36 per cent. Fourteen stool examinations were made and on one occasion cysts of E. histolytica were found. No other parasites of significance were noted. Proctoscopic examination was said to be negative. No statement regarding the size of his liver or spleen was recorded. He returned to his unit improved following treatment for amebiasis, but continued to have short bouts of explosive, cramping diarrhea, with eight to ten stools a day for periods of one to three days every two to four weeks. He noticed neither blood nor mucus in his stools and did not recall experiencing pruritus, urticaria, edema, or myalgia during the early course of his illness.

Following his discharge in December, 1945, he noted listlessness and gradual weight loss from 190 to 170 pounds. He fatigued easily but was able to carry on his heavier chores except during spells of diarrhea. One month prior to his admission he first experienced severe, persistent right upper quadrant pain and tenderness which was associated with anorexia. Activity intensified the pain. These symptoms persisted and he noted, in addition, profuse night sweats, recurrent diarrhea, and weight loss of five pounds. There was no nausea, vomiting, hematemesis, melena, dark urine, or jaundice.

He had a past history of jaundice at age eleven and yellow fever vaccination in 1942.

Physical examination on admission revealed a well-developed, well-nourished, six-foot white male weighing 165 pounds. His heart and lungs were normal. Blood pressure was 105/68, pulse 65. His liver was palpable 1 to 2 cm. below the costal margin in the midclavicular line and was soft, smooth, and exquisitely tender. There was percussion but no compression tenderness over it. The spleen was not palpable. Moderately enlarged, nontender lymph nodes were felt in the left axilla and in the inguinal regions. Rectal examination was negative. Neurological examination was normal.

Laboratory findings on admission were hemoglobin 15.2 gms. per cent and white blood count 7,350 with 42 per cent pmns., 42 per cent lymphocytes, and 15 per cent eosinophils. Four subsequent blood counts showed approximately the same total count and eosinophilia of 5, 6, 7 and 20 per cent. Sedimentation rate varied from 1 to 3 mm. per hour. Eight urinalyses were negative. Serology was negative. Ten stool examinations for parasites were made during the first four weeks of hospitalization and all were negative with the exception of the first two which contained whip-worm ova. Blood bilirubin was normal on repeated occasions. Eight urine examinations for bile were negative. Two-hour urine urobilinogen values varied from 0.52 to 2.81 Ehrlich units. Cephalin cholesterol flocculation was 3+, 4+ on admission and subsequently dropped to 2+, 2+ over a period of five weeks. Bromsulfalein (5 mg. per kilo dose) retentions on two occasions were 2.8 and 5.5 per cent in forty-five minutes. Routine blood agglutinations, including brucellosis and heterophile antibody titres, were negative. Chest x-ray, flat plate of the abdomen, and barium enema were negative. Proctoscopic examination revealed normal rectal mucosa. The electrocardiogram, which was normal on admission, showed depression of the T waves in the limb leads following a course of emetine.

Hospital Course.—The patient was afebrile except for a slight rise in temperature during the third to fifth

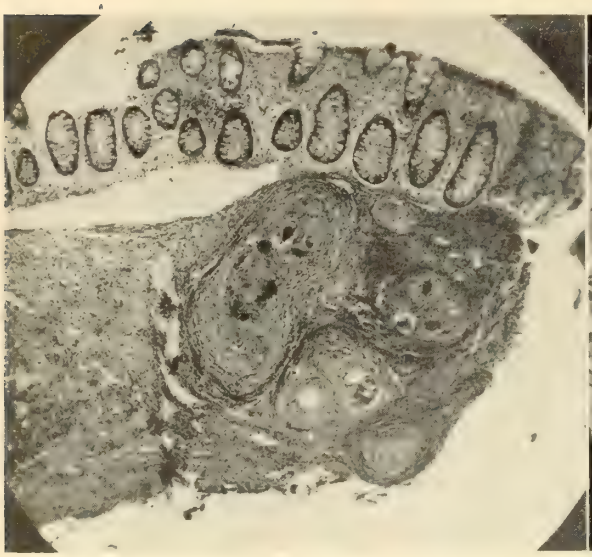

Fig. 1. Biopsy specimen from the superior valve of Houston. Low magnification showing submucosal pseudo-tubercles containing nests of Schistosoma japonicum and giant cells. The largest ova measure 60 x 120 micra, and most have thin highly refractile membranes. There is a moderately severe chronic inflammatory reaction surrounding the pseudo-tubercles.

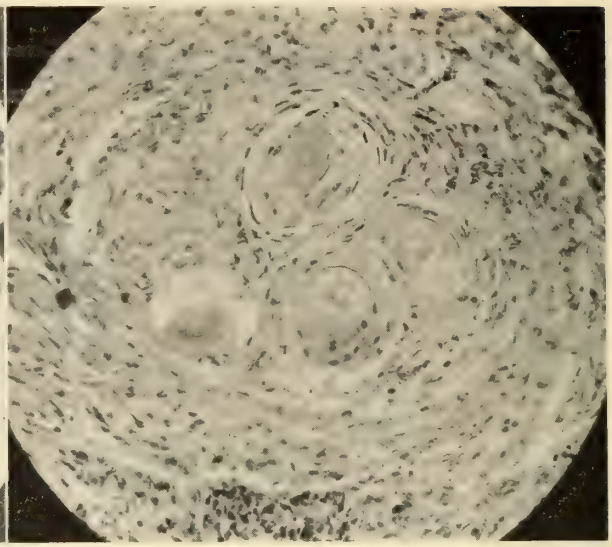

Fig. 2. High power magnification showing encapsulated ova within a pseudo-tubercle.

weeks when he developed an acute left salpingitis and catarrhal otitis media for which he was given penicillin. He was suspected of having amebiasis on admission and was given a course of emetine and diodoquin without effect on his symptoms or course. He continued to have pain and tenderness in the right upper quadrant and his liver increased in size slightly. His spleen became palpable, the enlargement reaching its maximum in the third week when it was 3 cm. below the costal margin. It was never tender. During the fourth week his liver and spleen began to recede and his symptoms improved. By the fifth week the liver was barely palpable, the spleen not palpable, and by the sixth week neither was palpable. There was no correspondence between physical findings and liver function tests. The patient was discharged at the end of the sixth week of hospitalization with the diagnoses of atypical infectious hepatitis and trichuriasis. No treatment was given for the latter because of the liver disease.

Second Admission.—By the time he had reached his home, after a jolting 120-mile bus ride from the hospital, he had recurrent symptoms with pain in the right upper quadrant, malaise, and weakness. He remained at home two weeks during which he noticed in addition enlargement of the lymph nodes in both femoral fossae, particularly the right, and associated weakness of his right lower extremity. He was readmitted to the hospital on November 26, 1947, at which time his liver was enlarged and tender 3 cm. below the costal margin and his spleen was palpable 5 cm. below the costal margin. A moderately enlarged lymph node was again felt in his left axilla in addition to large nodes palpable in the inguinal and femoral regions. Otherwise the examination was unchanged.

Laboratory findings this time revealed the hemoglobin and sedimentation rate to have remained essentially unchanged. White blood count range was 3,500 to 9,000 with pmns. 35 to 63 per cent, lymphocytes 30 to 51 per cent, and eosinophils 2 to 19 per cent. The average of nineteen white blood counts up to the time therapy was completed was 5,370. The average percentage of eosinophils was 13. Bromsulfalein retention was 2 per cent in forty-five minutes. Cephalin cholesterol flocculation was 1+, 2+. Cholesterol was 196 mgs. per cent with 127 mgs. per cent esters. Alkaline phophatase was 7 King-Armstrong units. Plasma proteins were total 7.8, albumin 4.5, and globulin 3.3 gms. per cent. From the time of readmission until completion of therapy with tartar emetic, a period of twelve weeks, thirty-five stools were examined for Schistosoma ova with negative results. Twenty-four of these showed whip-worm ova. The methods of examination for Schistosoma ova included (1) direct smears, (2) gravity sedimentation, (3) modified acid-triton-ether centrifugation, and (4) egg-hatching. Proctoscopic examinations before therapy were negative on four occasions. During three of these examinations scrapings of the anal crypts and rectal mucosa were examined for ova without success. On the fourth examination two punch biopsies were taken from each of the inferior and middle valves of Houston.

Urinalyses were normal. Chest x-ray was negative. Electrocardiograms taken during therapy showed progressive reduction in the amplitude of T waves in the limb leads and development of diphasic T waves in the chest leads. Within four days after completing therapy the T wave depression became less pronounced. A complement fixation test with Schistosome antigen was negative during the third week following readmission, and a skin test with mixed Schistosome antigen (obtained through the courtesy of Dr. Harry Most) was negative during the seventh week.

Hospital Course.—Following readmission schistosomiasis was suggested as a possible diagnosis and attempts were made to find the ova in the feces without success. Bone marrow aspiration at this time revealed myeloid-erythroid hyperplasia with moderate eosinophilia of the marrow. Biopsy of a lymph node in the left axilla showed benign hyperplasia. Two liver biopsies were done during the second and eighth weeks, both showing slight to moderate increase in the number of lymphocytes in the portal spaces and slight increase in the number of eosinophils. No definite diagnosis could be made from them. The patient's symptoms improved on bed rest. By the third week his liver and spleen had receded somewhat, being palpable 1 to 2 cm. below the costal margin. They were stationary thereafter until the ninth week, after which the liver could not be felt below the costal margin, the spleen remaining as before. The liver tenderness decreased progressively.

During the seventh week rectal biopsy was attempted at the suggestion of Dr. C. J. Watson, despite a normal mucosa. Four pieces of tissue were removed, one of which contained ova of Schistosoma japonicum (Figs. 1 and 2). Therapy with tartar emetic was instituted, a total of 444 c.c. of a 0.5 per cent solution of antimony and potassium tartrate (0.799 gms. antimony) being given over a period of five weeks, following the procedure of Most.[7] Toxic reactions were transitory pain and stiffness in the muscles, nausea, and depressed T waves in the electrocardiogram. By the time treatment was completed the patient noted appreciable relief from his right upper quadrant pain and felt stronger. Rectal biopsies were repeated upon completion of therapy, fragments being taken from each of the three valves of Houston. The fragment from the uppermost valve showed submucosal pseudo-tubercles with nests of encapsulated ova similar to the pre-treatment biopsy. The other two fragments were normal.

During a three-week observation period following therapy for schistosomiasis the patient remained asymptomatic. His spleen remained palpable 2 cm. below the costal margin. His liver was no longer tender. The white blood count, which had been depressed slightly, returned to normal levels, and the eosinophilia dropped from 18 to 5 per cent. His whip-worm infestation was successfully treated with leche de higueron. He was discharged during the fifteenth week of his second admission, a total of twenty-three weeks since he was first hospitalized.

Discussion

Clinical Course.—The course of schistosomiasis japonica is customarily divided into three stages of variable length.[1,2,7,11]

The *first stage* or incubation period begins with the penetration of the body by the cercariae and ends with the pairing of the mature worms in the mesenteric vessels. It generally lasts five to seven weeks.

In the *second or acute stage* the female worms deposit eggs in the small vessels of the intestinal wall from which some are extruded into the lumen, and others are carried into the draining lymph nodes and liver as well as other abdominal organs. This stage generally lasts about three to four months. The symptoms of the first and second stages overlap greatly.

In general, in addition to new findings, there is accentuation, during the latter stage, of the symptoms which began to appear during the incubation period. The findings that one may note during these periods are the following: local pruritus, urticaria, edema, cough; chills, fever, sweats, headache, lethargy; myalgia, arthralgia, rigidity on neck rotation; anorexia, diarrhea, weight loss, fatigue; abdominal fullness, pain, and tenderness; enlarged tender liver, splenomegaly; eosinophilia, yellow nodules in rectosigmoid; jaundice, anemia, leukocytosis. In addition lung infiltrations, skin lesions, neurological complications, and vascular occlusions in the toes are occasionally encountered.

The *third or chronic stage* is a period of continued tissue destruction and proliferation. It is properly subdivided into early chronic and late chronic periods. The former is a prolonged interval of gradual tissue fibrosis about which relatively little is recorded in the literature. The latter appears about three to five years after the onset of the disease and is characterized by the development of hepatic cirrhosis and its consequences; splenomegaly; thickening and fibrosis of the intestinal wall, mesentery, and omentum; papilloma formation; and general deterioration and debility.

The clinical course as classically described has been based by and large on observations in native populations where multiple parasitic infestations, reinfection, and nutritional deficiencies are common. It seems logical to expect that the course among healthy American soldiers who were usually exposed a relatively short time and whose nutrition was carefully maintained should be modified appreciably, particularly in those treated early. Such was the case in a large group of patients seen by Mason et al[6] during the early chronic stage of the disease, about six months after the acute process had subsided.

The present case was diagnosed three years after exposure and represents a later phase of the early chronic stage of the disease. Despite the prolonged course, recurrent clinical manifestations, and lack of treatment, he appeared well-nourished and, with the exception of the periods

when diarrhea recurred, was able to keep up his farm duties. Liver function studies at the height of his illness showed but slight abnormality, and two liver biopsies showed essentially normal tissue with slight evidence of chronic inflammation in the portal spaces. X-ray studies of his gastrointestinal tract were normal. Thus he presented fewer abnormalities than one might have anticipated at this time from the textbook descriptions of the disease. It appears not unlikely that the progress of the pathological process in Americans may be retarded, prolonging the early chronic phase of the untreated disease several years beyond its usual duration as classically described. With this in mind one is less likely to rule out a potential case because the abnormalities present are not commensurate with the duration of symptoms.

Rectal Biopsy.—Diagnosis of schistosomiasis has until recently depended upon finding the ova in the stools. This is at best a tedious process. In the chronic stages and mild infections there are characteristically few ova in the feces, and diagnosis by this means is particularly difficult. Serological and skin tests have been developed but as yet are of lesser value. A recently developed procedure that holds great promise is the rectal biopsy technique which has been found of value in Schistosoma mansoni infestation. The procedure was originated by Ottolina and Atencio[9] in 1943 following the demonstration that the highest incidence of schistosomiasis at autopsy was obtained by examining digested tissue from the upper half of the rectum. They applied this to patients by taking biopsies of rectal mucosa from the first (inferior) rectal fold, and found that of 140 cases whose stool examinations were consistently negative for ova, 14 per cent were positive on biopsy. Their procedure consisted of digesting the biopsied tissue fragment with 4 per cent KOH while incubating it at 60 to 80° C. The digested material was then centrifuged and the sediment examined for ova. Rincon-Urdaneta,[10] using the same procedure, found positive rectal biopsies in 42 per cent of 128 cases. Geib, Sher, and Cheney[3] applied this technique to 46 Puerto Rican patients. Thirty-four of these patients had been untreated, and twelve had been treated with 45 c.c. of fuadin one week prior to examination. The relative percentages of positive results by biopsy and stool examinations are listed in the following table:

	No. Cases	*Biopsy*	*Stool*
Untreated	34	50%	29%
Treated	12	67%	8%
Both	46	54%	24%

Hernandez-Morales and Maldonado[4] modified the technique by biopsying the first rectal valve, compressing the piece of tissue between two microscope slides, and examining it under low power. They studied 138 cases of Schistosoma mansoni infection including 50 untreated and 88 treated patients. The results of biopsy were compared with stool examinations by an acid-ether concentration technique and the following relative percentages of positive results were obtained:

	No. Cases	*Biopsy*	*Stool*
Untreated*	50	100%	42%
Treated	88	70%	18%
Both	138	81%	26%

*In two instances stools were not examined, therefore 42 per cent is based on 48 cases, 26 per cent on 136 cases.

In 1947, Ottolina[8] reported on a similar method of direct examination in which the tissue fragment is immersed in fresh tap-water for three to five minutes making it more transparent (by dissolution of hemoglobin) and allowing more adequate visualization of ova when the tissue is compressed between two slides.

To date, no reports have appeared describing the efficacy of rectal biopsy in chronic Schistosoma japonicum infection. It is reasonable to anticipate good results, however, in view of the demonstration that "yellowish nodules" (containing nests of ova) on the mucosal surface of the lower sigmoid and upper rectum are commonly found in the acute stage of schistosomiasis japonica.[2,5] Johnson and Berry[5] found the yellow nodules on sigmoidoscopic examination in 67 per cent of sixty-three patients suffering from acute infections. The nodules were small, firm, 1 to 3 mm. in diameter, and occurred in clusters of three to twenty-five beneath the mucosa. They were most abundant at the rectosigmoid junction, and they extended up into the lower sigmoid and down 4 to 5 cm. in the rectum. Biopsy of these nodules revealed clusters of ova beneath the mucosa. Presumably many of these ova become trapped in the tissues by the proliferative reaction they stimulate.

In the present case, nests of Schistosoma japonicum ova were found surrounded by dense concentric fibrous tissue (pseudo-tubercles) beneath the mucosa in the stained sections, though the entire mucosal surface appeared normal on sigmoidoscopic examination. Biopsies were taken initially from the middle and inferior valves of Houston,

the positive one (of four) coming from the former. Following therapy with tartar emetic biopsies were repeated, specimens being taken from the superior, middle, and inferior valves. The biopsy from the uppermost valve was positive; no organisms were found in the other two. The presence of ova in the upper valves and not in the lower is consistent with the findings in the acute cases in whom the greatest concentration of yellowish nodules was found at the rectosigmoid junction, the numbers decreasing below that point. It seems advisable therefore in the case of Schistosoma japonicum infections to secure the tissue fragment from the upper valves of Houston or the rectosigmoid region, rather than the inferior valve as recommended by Hernandez-Morales and Maldonado in Schistosoma mansoni infections. The particular method of examining the tissue may vary. Direct examination of the compressed unfixed tissue has the advantage of simplicity and enables one to differentiate live from dead ova easily. Stained sections allow more accurate delineation of tissue histology, and minimize the likelihood of overlooking light infections where only few ova are present. This presupposes that the entire fragment is sectioned and examined. A given biopsy specimen may be examined to good advantage by both methods.

Summary

1. A case of chronic Schistosoma japonicum infection, which was first diagnosed by means of punch biopsy of a valve of Houston, is presented.

2. The possible alterations in the time sequence of the pathological changes of schistosomiasis japonica in the American soldier are discussed.

3. The published articles on rectal biopsy in the diagnosis of schistosomiasis are reviewed, and the rationale for its use in chronic Schistosoma japonicum infections is presented.

OCCUPATIONAL THERAPY COURSE APPROVED

The American Medical Association Council on Medical Education and Hospitals has now approved the University of Minnesota's course in occupational therapy.

Organized in 1946 in the physical medicine department of the medical school under the direction of Miss Borghild Hansen, the course is designed for the training of occupational therapy technicians.

Bachelor of science degrees in occupational therapy were awarded last June to twelve students constituting the first class to complete the course which requires four and one-quarter years of classroom and technical training. Application for approval of the course by the council was made upon the graduation of the first class.

Before the organization of the course in the medical school, a pre-occupational therapy program was offered in the University's college of science, literature and the arts.

At the University of Minnesota Hospitals, the occupational therapy division maintains a clinic for hospital patients and out-patients as well as a bedside occupational therapy service for those unable to come to the clinic. An extensive occupational therapy program is also available to psychiatric patients.

PROTECTIVE VACCINATION AGAINST TUBERCULOSIS, WITH SPECIAL REFERENCE TO BCG VACCINE

JOSEPH DAVID ARONSON, M.D.

Associate Professor of Bacteriology, Henry Phipps Institute, University of Pennsylvania

Philadelphia, Pennsylvania

For twenty-five years, BCG (Bacillus Calmette and Guerin) has been widely used to increase resistance to tuberculous infection among population groups in which there is a high incidence of tuberculosis and among persons whose occupation, the care of the tuberculous, increases their danger of contracting the disease.

In spite of its widespread use, BCG has not received universal acceptance due to the fear that the culture is not a virus fixe, as claimed by Calmette, but that it might regain its virulence. The innocuousness of the BCG vaccine for man is proved by the fact that not a single unequivocal case of tuberculosis can be attributed to its use. Since the first results of BCG were reported in 1921, more than ten million people, largely in the Scandinavian, European and South American countries, have received the vaccine as a protection against tuberculosis.

The value of BCG vaccine in increasing resistance to tuberculous reinfection has been investigated under carefully controlled conditions among some Indians of the United States and Alaska, in a study directed through the U. S. Office of Indian Affairs and the Henry Phipps Institute, University of Pennsylvania. Freshly prepared BCG vaccine was administered intracutaneously to 1,551 American Indians ranging in age from less than one year to twenty years and to 123 newborn infants. At the same time 1,457 Indians of comparable age and living under the same conditions received an intracutaneous injection of sterile physiological saline and served as controls. One hundred and thirty-nine newborn infants also served as controls. No untoward local or general reaction followed the injection of the vaccine. In no instance did the regional lymph nodes ulcerate.

The original group of vaccinated and control were followed over a period of from nine to eleven years by means of tuberculin tests and roentgenograms of the chest, while the group of "newborn" infants were similarly followed for from six to eight years. The vaccinated cases were observed for a total of 16,406 person-years and the controls for 15,207 person-years. The mortality rate from all causes was 3.1 per 1,000 person-years of observation for the vaccinated and 7.2 for the controls. Among the 1,551 BCG vaccinated there occurred a total of 55 deaths, including 6 deaths from tuberculosis. Among the 1,457 controls there occurred a total of 109 deaths, including 53 deaths from tuberculosis. The mortality rate from tuberculosis per 1,000 person-years of observation was 0.4 and 3.5 for the vaccinated and controls, respectively.

Among the controls, the death rate from tuberculosis was highest among the males in the fifteen to nineteen and twenty to twenty-four year age group and in the females in the ten to fourteen and fifteen to nineteen age group. It was approximately twice as high among the females as among the males. Among the 123 newborn infants who were vaccinated and observed for from six to eight years, seven have died, none from tuberculosis. Among the 139 newborn controls fifteen have died, four of them from tuberculosis.

The tuberculin reaction became positive one year after vaccination in 19.3 per cent of cases and has remained at approximately the same level throughout the course of this study. Among the controls the tuberculin reaction became positive in 12.7 per cent within one year after the initial negative reaction, and there has been a constant and gradual increase in the percentage of the controls reacting to tuberculin. Roentgenologically demonstrable lesions having the characteristics of primary tuberculosis occurred in twenty-two of the vaccinated and in 120 of the controls. Minimal lesions of reinfection type, progressive lesions and miliary and extrapulmonary lesions of tuberculosis were found in twenty-one of the vaccinated and in ninety-three of the controls.

Abstract of the fourteenth annual John W. Bell Tuberculosis Lecture, delivered before the Hennepin County Medical Society, May 3, 1948.

THE NINE BILLION

The April issue of the *News Letter* carried a short note on the whereabouts of some nine billion in social security funds. The American Bar Association has recently shed a bit of light on this whereabouts. An A. B. A. resolution (American College of Radiology News Letter, June, 1948) reveals "(1) That 99.5 per cent of the funds thus far accumulated under the Act have been spent on public projects, and that special non-negotiable Government obligations have been substituted 'for 86.26 per cent thereof.' (2) That 'such part of such sum as may be necessary to meet extraordinary demands which may arise in the future will of necessity have to be raised by the sale of negotiable bonds or by the imposition of taxes to redeem the non-negotiable obligations.'"—*News Letter,* Council on Medical Service, A.M.A., August 12, 1948.

History of Medicine In Minnesota

NOTES ON MEDICINE IN FREEBORN COUNTY, 1857—1900

ANDREW GULLIXSON, M.D.
Albert Lea, Minnesota

(Continued from November issue.)

Dr. Frank A. Blackmer was born at Amherst, Ohio, January 16, 1846. He came to Freeborn County with his parents in 1856. They located on a part of what is now known as Blackmer's addition to the City of Albert Lea. He aided his father in driving his ox teams from McGregor, Iowa, at that time the terminus of the nearest railroad, across the prairies to their new home. He was then ten years of age. He found plenty of gravel in his diet as a youngster, and continued to find it there up to his early manhood. He began his schooling at Amherst, Ohio, and attended the public schools of the then struggling village of Albert Lea.

At the age of twelve, two years after his arrival here, while working in the fields one day, he came to the conclusion that he would strike out for himself, and hanging his scythe in a tree, he came to town to get work. He did odd jobs and soon accepted a position with the year-old newspaper, *Southern Minnesota Star,* begun in April, 1857. Here he learned to set type. Shortly thereafter, probably in 1859, Dr. A. M. Burnham needed someone to publish his *Freeborn Springs Herald* at Itasca, and secured young Master Blackmer for the position. But Dr. Burnham's hopes and aspirations of Itasca as a county seat failed to materialize, and young Blackmer with his conniving young partner loaded the fonts of type and the hand-press by night and carted them to Blue Earth and founded the *Blue Earth Post,* which continues still to be one of the most influential journals of the state. Dr. Burnham was paid $200 about two years later. He was paid at night, and probably in the dark of the moon.

In 1862, at the age of sixteen, young Blackmer enlisted in Company C, Fifth Minnesota Volunteers Infantry, and with the rank of Orderly Sergeant, was sent with his company to the frontier to protect settlers from threatening Indian outbreaks. On August 22, 1862, his company participated in the battle of Ft. Ripley, and there young Sergeant Blackmer received a severe gun-shot wound involving the face, jaw, and tongue. In consequence of this disability, he was discharged in October of the same year. The ball was removed by Assistant Surgeon A. A. Ames of Minneapolis. This wound, with the resulting scars on his face and tongue, was the cause of much discomfort to him during his life. After his discharge, hospitalization, and convalescence, he went to Chicago and during the winter worked as a compositor on the morning papers. In 1863 he entered the academic department at Oberlin College, Oberlin, Ohio, and sawed wood, set type, and did other work to pay tuition and board. He had already decided to study medicine, and while at Oberlin he spent some time reading medicine in the office of one Dr. Bruce. After his courses at Berlin he became a student at Cleveland Medical College, Cleveland, Ohio. After graduating there in 1868, he returned to Albert Lea, married a Miss Prescott, and became a partner of Dr. Wedge, both in Dr. Wedge's drugstore and in his medical practice. Within a year, Dr. Blackmer's young wife died, and he went to Blue Earth and worked on the paper he had

founded there. Later he went to Jackson, Minnesota, acquired lands, and farmed. But fortunately for Freeborn County, the grasshoppers forced him to discontinue this venture. He returned to Albert Lea October 15, 1872, married Frances E. Wedge, a cousin of Dr. Wedge, and began in earnest a highly successful medical practice that continued until his death July 11, 1900.

Dr. Blackmer had one son, Ray, a daughter, Anna, and four brothers: Heman, a lawyer; Henry and Loren, farmers; and Nelson, who died young. He was a devoted husband and father and a loyal comrade and citizen. He was energetic, ambitious, and generous. He loved his fellow men and none were denied his services when requested. He was particularly kind and helpful to boys and young men.

"Dr. Blackmer was one of the talented, successful physicians and surgeons of the state. As a surgeon, he became eminently adept and modern in his methods. In performing an operation he was seemingly relentless, yet he was at all times sympathetic and gentle as a woman."—*Standard,* July 11, 1900.

"Dr. Blackmer will leave for Washington, D. C., as a delegate to the annual convention of the American Medical Association. This is an honor well deserved and one which the genial doctor will improve in the interests of his noble profession."—*Standard,* April, 1884.

"In driving across the lake, following the course of travel, the ice suddenly broke under Dr. Blackmer's team, with horses and sleigh sinking in about five feet of water. He narrowly escaped by jumping, while his horses went under. Help was obtained and the team was rescued."—*Enterprise,* February, 1884.

The following was told by one of his then youthful friends who later became a dentist:

"Walking with Dr. Blackmer one morning an anxious mother rushed toward them crying, 'Come quick, my daughter is dying!' One look told the story. The doctor pulled out his jackknife, wiped it on his boot, and readily performed the urgently needed tracheotomy. The youth held a spoon in the trachea while the doctor whittled a tube from a spool, inserted it into the trachea, and tied it with a cord around the neck. Results: good."

"Dr. Blackmer took a span of horses on a bad debt. The horses had killed the husband of the woman who owned them, in a runaway last spring, and so he was on guard and watchful in managing them. As soon as they were driven into the street he found that he had underestimated the viciousness of the brutes. They ran fiercely and as he was unable to hold them in a turn, the buggy was hurled with terrible force. The doctor and his companion were severely injured—the doctor now with his leg in a cast, and his companion unconscious."—*Standard,* June, 1893.

"Dr. Blackmer's life was most active. He was a successful business man and financier, and accumulated a handsome fortune."—*Standard,* July 11, 1900.

"Dr. Blackmer's keen interest in medicine and surgery prompted his regular attendance at state and national medical society meetings. He also traveled a good deal and took clinical trips. In November, 1890, together with his wife, he sailed for Europe, and after a short tour of France and Italy, he spent the winter in clinical work in London. He wrote as follows, from London: 'We are attending clinics all the time and do not have time to see anything unless it comes in our way as we pass from one hospital to the other. I have seen more surgery that I can think of. We are observing thirty cases of Koch's treatment. It seems to help in lupus, but in the acute consumption of the lungs is very uncertain. It seems to help some cases of tuberculosis of the joints. I can see that the winter is going to be very busy, but very profitable. There is no end of surgery. I saw nine or ten operations on the eye at Mowesfield hospital in the forenoon, and afternoon saw operations for the radicle cure of hernia at Guy's hospital. After surgery, ward walks reveal all manner of surgical diseases and procedures. We are treated with the greatest cordiality and good fellowship'."—*Standard,* December 16, 1890.

"Dr. Blackmer was one of the best known pioneers of southern Minnesota by reason of his medical attainments and army record. He had not been very well for several years, but not until about a month before his demise, did he go to Chicago for consultation and diagnosis. Dr. J. B. Murphy, among others, agreed that his ailment was deemed to be due to gall stones,

and an operation was declared to be imperatively necessary. He anticipated fatal results, arranged his affairs, and entered Northwestern hospital under Dr. Moore, who operated July 3. He died July 11, 1900. His death was a great loss to the community and to the profession in which he was highly distinguished. A large concourse of old settlers, friends, old soldiers, and members of the medical profession gathered at the funeral, and during that hour, business in Albert Lea was suspended."—*Standard,* July 18, 1900.

J. F. Kelsey appeared April 20, 1865, with the following card:

"Go tell the world these blessed things; yes, be sure your patrons hear, that henceforth I enter my name with the laity of Freeborn County to labor in the field of true medical science, embodied in the various departments of natural, economical, and metaphysical science, to the elucidation, prevention, and cure of diseases, which is, in fact, the highest development applied to the noblest temporal objects, namely: the prevention and alleviation of human suffering and the prolongation of human life. Hence, I offer my services to the people of this vicinity who are so unfortunate as to be afflicted with disease, as an intelligent and efficient helper and guide of nature, in regaining their natural standard of action, or what we call health. Their patronage is solicited. Truly, J. F. Kelsey, M.D."—*Standard,* 1865.

This colorful card appeared only a few times and is the only contact found. Where and when that insatiable enemy of immortality caught up with him is not known.

Dr. William Henry Smith, a physician for nearly forty years, and an army surgeon, was born in Denmark, Lewis County, New York, March 9, 1815. His parents, Selah and Catherine (Tisdale) Smith, were classed among the agriculturalists, the father being one of the first settlers in that part of the Black River country, and died when William was thirteen years old. From that date the son took care of himself. He was educated at common and select schools, taught six winter terms, beginning at the age of nineteen and receiving eight dollars a month and board, for the first season. The rest of the time he worked on farms and attended select schools. At the age of twenty-four he commenced reading medicine with Dr. Elkanes French, of his native town, and attended the last course of lectures held at Fairfield, Herkimer County, before the medical college was moved to Geneva. He received from the authorities of Jefferson County a certificate permitting him to practice, which he did for four years at Pamelia, Four Corners, in that county.

In 1846 he moved to Beaver Dam, Wisconsin, and practiced there for twenty years, except when in the army. In 1856, he attended a course of lectures at Rush Medical College, Chicago, from which he received his diploma. In 1862 Dr. Smith went south as surgeon of a Wisconsin artillery regiment. At the end of one year, he was transferred to the same position in the twenty-eighth Wisconsin Infantry and served three more years. During nine months of this time he was post surgeon at Pine Bluff, Arkansas. He was a very patient man and was very attentive to the wants of the sick and wounded. While in the South he contracted a disease from which he suffered more or less for a long time; and in 1866, thinking a change of climate might be beneficial, he went to Fulton, Missouri, practicing when he had sufficient strength.

In 1873, much improved, he returned to the North and settled at Albert Lea. Here he had a good practice and an excellent standing and held the office of county coroner. When at Beaver Dam during the administrations of Presidents Taylor and Fillmore, he held the office of postmaster. A Whig in early life, with Free-soil tendencies, he naturally drifted into the Republican ranks, where he is still found. For the last twenty-five years he has paid very little attention to politics except to vote. His leisure time is given mainly to medical studies.

On February 22, 1843, he was married to Miss Louisa M. Stevens of West Mar-

ginsburg, Lewis County, New York. They had three children. A son, Selah H., was accidentally killed on the railroad at Cherokee, Kansas, in January, 1874. Mary is the wife of Jasper J. Bond of Albert Lea; Frances E. and Charles Henry also both reside at Albert Lea. (*Freeborn County History,* 1882).

"Dr. Smith has resigned his office as coroner of Freeborn County, and his many friends will regret to learn that he has decided to remove from here. He will go to Wentworth, Dakota Territory, where his son resides and where he has valuable farms. He will also practice his profession there and undoubtedly will do well, for he is a physician of superior abilities and judgment, and will carry with him the high repute which he bares in all regards."—*Standard,* August 5, 1885.

Dr. George E. Moon practiced at Geneva a short time in 1869. Together with Dr. F. A. Blackmer and Dr. E. S. Gibbs, he read medicine with Dr. A. C. Wedge in 1867. He attended Cleveland Medical College and was a graduate physician and surgeon from there in 1869. After his short stay at Geneva he moved to Yankton, Dakota Territory. He made many friends there and was considered one of the best physicians and surgeons in Dakota Territory. "Consequently the town was considerably excited one evening in January, 1884, when he announced to his wife that he had deliberately taken a large dose of morphine, but was not going to die with his boots on. He began to pull them off and told his wife to get him a clean shirt. A physician was called, but he died the next day."

Charles W. Ballard was born in New York City in January, 1826. He attended boarding schools in New York and New Jersey. In 1847 he began the study of medicine at Washington Medical University of Baltimore and the College of Dental Surgery there and in 1850 graduated from both institutions. He married Miss Anna E. Harris the same year.

He was a member of the state senate for two terms, taking a decided stand against slavery. He then located in North Carolina and practiced his profession there for ten years, after which he returned to New York and Connecticut, where he engaged in business. In 1868 he went to Florida for his health, remaining there for two years. In 1870 he came to Freeborn County and purchased lands within and near the borders of Albert Lea. His interests were entirely in real estate, horticulture, travel, and writing his observations. He was a well-educated gentleman of good judgment and much wisdom and an outstanding citizen, benefactor, and friend. He did not practice his professions at any time in Albert Lea. Later in life he returned to Sarasota, Florida, where he died.

Dr. Tilly Peabody was an herb doctor, not a medical graduate. He came to Freeborn County in the early days, probably in the late 1860's. Records show that in 1875, he homesteaded on the southeast quarter of section thirty-five, Alden Township. He practiced in the southwestern part of this county and the adjoining Winnebago County in Iowa. Nothing concerning him is found in the newspapers or pioneer histories. Rumors had it that he was a scion of a prominent family in the East and that a wealthy sister made trips to this section, endeavoring to have him return. Two old people, now past the age of ninety years, remember him as "a kind doctor who did a lot of good." They tell that, with his wife, he would roam the Bear Lake woods, collecting in season the various roots, herbs, and leaves from which he made his own medicines, salves, and plasters. He traveled on horseback. Perhaps it was he of whom a pioneer Iowa doctor related the following incident to the writer over forty years ago.

"The doctor, when answering a call found his patient suffering from urinary retention, and not having the necessary catheters in his meager saddlebags, cut a suitable stem from a castor-bean stock, scraped it down to its well lubricated smoothness with his jack-knife and relieved his patient successfully."

His wife evidently died, as his last known abode was in a dugout shared with a Norwegian family in Winnebago County, Iowa. The only son of that family, now an old man, resides at Lake Mills, Iowa, and is known as Peabody Nels. Dr. Peabody died in 1887 and was buried in Bear Lake Cemetery.

Dr. E. M. Gibbs was born at Rome, Bradford County, Pennsylvania, in 1847. His father and family were early pioneer residents of Freeborn County, located at Geneva. He attended schools at Albert Lea, and in 1867, together with Dr. F. Blackmer and George E. Moon, read medicine with Dr. A. C. Wedge. In the spring of 1869, he graduated from Cleveland Medical College and later the same year announced the beginning of practice at Geneva. "He brings into the profession the benefits of his careful reading and exemplary habits."—*Standard,* 1869. He practiced at Geneva only one year and then moved to Monticello, Minnesota, where he was in active practice for many years until he died from a cerebral hemorrhage in 1922 at the age of 75. He was buried in the family plot at Geneva.

Dr. Alvin H. Street was born in Orange County, New York, in April, 1833. He was one of two sons born to Chapin and Dolly (Ness) Street. His mother died in New York. His father, a school teacher and a large landholder, was an imposing aristocrat, who later moved with his family to Hebron, Illinois, where he acquired large land holdings and resided until his death.

Dr. Street attended the academies at Albion and Kerryville, Illinois. He subsequently graduated in both medicine and dentistry in his native state and practiced there until he was thirty-six years of age, when he decided to try his fortune in Minnesota. He located at Albert Lea in 1869, paying most attention to medical practice but keeping a hand in dentistry at all times. He disliked the trials and hardship of pioneer medical practice and in 1876 returned to New York for postgraduate work in dentistry. He returned with equipment for making dentures, introduced "laughing gas" for use in extractions, and no doubt was well qualified to do creditable work in that field. But his interests gradually shifted elsewhere. He became neglectful of his office and his appointments and gradually faded out of both of his professions. He never married. He died at the home of his niece at Alden in 1914 and was buried in the family lot at Hebron, Illinois.—*Freeborn County History,* 1911.

Dr. Street was an odd and eccentric man and held no appeal for the ladies. He was a vegetarian and always carried crackers and nuts in his pockets. He was scrupulously clean but dressed in shoddy clothes. He would walk out to his nearby farms, and in season would remove his foot wear in order to walk in the mud. Also in season he would take to the deep clover fields, disrobe, and take sunbaths. He became interested in agriculture and spent the winter of 1890 at the agricultural college. His library was filled with books and pamphlets on the subject.

Dr. Street was an honorable, upright, honest gentleman. He had a keen sense of values. He bought and sold lands and town properties, loaned money, and became quite wealthy. He was a boyhood schoolmate of the great Pullman, in Orange County, New York. He called himself a paroled Methodist, having acquired that status by attending a dance at the age of fourteen. He never returned to the fold but gave generously to the church, besides making a gift of $10,000 to the Albert Lea Ladies' College. If any notice appeared in the newspapers about his gifts, he

would immediately cancel them. After the year 1900 he lived with his tenant on his farm near Alden. He then began to travel a great deal. He made frequent trips to New York and to Arizona for his health. He owned a fine store building on Albert Lea's broadway, but when he died the executors of his will could not for some time find his safe containing his deeds and papers. Later it was found in a dingy corner on the upper floor of a nearby building. He may not have contributed much to pioneer medicine but he was an honest, honorable friend and citizen.

Dr. John H. Froshaug located at Albert Lea in 1871 and practiced here until 1877. Nothing can be found concerning his birthplace, early education, or medical training. He was evidently of Scandinavian parentage. He was well regarded, as the following news item indicates:

"Dr. John Froshaug had a lot of friends in town that would have been glad to have seen him retain his office, a small one which he owned and was furnished with all modern equipment, including a mortgage. Money, the root of all evil, was used to root him out; and a man on an independent ticket, with plenty of money, sold him out."—*Enterprise,* 1876.

"Dr. Froshaug associated with Dr. Blackmer in the drug business, drugs, chemicals, and patent medicines."—*Enterprise,* May 18, 1876.

In July, 1877, he moved to Lake Park, Becker County, and in 1879 was a delegate to the Republican State Convention from that county. Later he moved to Twin Valley and died there June 20, 1889.

R. D. Barber.—The following account is given of one R. D. Barber:

"At an early day (1871), a man named R. D. Barber, calling himself a doctor, located in the village of Alden and commenced 'peddling pills.' He remained less than a year, as he was unpopular, and then left, locating at some point in the southwestern part of the state, where he again made himself odious by transporting a brother (who, he insisted, was crazy) to an insane asylum and then charged an enormous bill for his services. The bill was paid but gave him the reputation he deserves. His whereabouts at present is a mystery, to the satisfaction of all who knew him."—*Freeborn County History,* 1882.

Dr. Sylvester S. Bedal was born at Kensington, Canada, September 10, 1847. Nothing is known of where he received his early education, but evidently it was classical and extensive. When he went to Chicago is not known, but he was for three years a student at the Chicago Medical College, including 1871, at the time of the great fire there. He received his M.D. degree from this college and located at Albert Lea, May 30, 1872. He practiced here until September, 1874, about two and a half years. A very modest card appeared in the newspaper announcing "S. S. Bedal, Physician and Surgeon. Office over The Red Drug Store." No one now living here remembers him. Except for the newspaper files containing reprints of three letters received from him in 1874, this young pioneer physician, apparently a "gem of purest ray," would have been lost to our record.

Under appointment from the State of Minnesota as a candidate for Assistant Surgeon in the United States Army, he went to New York City, passed the examinations, and served from September 17, 1874, until his discharge in 1877. Information as to his place of birth and death, his medical education and place of graduation, together with data on his army service, came from the files of the Adjutant General's office. He must have been a quiet, unassuming, well qualified physician and surgeon and, too, a gracious, gallant, and lovable character.

In his letter dated August 23, 1874, he speaks of a day and night of jolting on the train that brought him to Chicago and remarks about the wonderful progress

in rebuilding after the fire. Then two nights and a day brought him to New York City. He writes:

"I am visiting places of interest every day but more especially such as interest me professionally, as the prisons, hospitals, and asylums on Blackwell and Ward islands, and public libraries, museums of anatomy, medical colleges, et cetera, and find them to be excellent sources of instruction."

In a letter dated September 24, 1874, in which he speaks about his examinations before the army medical board, he says:

"The manner of conducting examinations gave me a high opinion of the professional ability of the medical corps of the United States Army. The recorder conducted me to a private room and caused me to certify on my honor as to my age and my mental and physical condition. Being ushered into the examining room of the full board, consisting of five officers, uniformed in cavalry rig, I was politely invited to occupy a vacant chair in the circle and was addressed by one, somewhat after the following manner: 'Doctor, how long have you been in practice?' 'In what part of Minnesota have you lived?' 'Is that much farther north than New York?' I gave the latitude of both places. 'How low have you known the mercury to be there?' 'Why is mercury used in constructing a thermometer?' 'Explain the principle of contraction.' I answered these successive questions to the best of my ability, alluding to the contraction and expansion of bodies by cold and heat. 'What do you call the process of ascertaining the relative densities of bodies?' 'How would you find the specific gravity of bodies lighter than water?' 'And of liquids?' This manner of asking questions continued until I was taken through natural philosophy, mathematics to logarithms, and the Latin language. The next examination commenced with ancient Greeks, Persians, Babylonians; and they asked me questions up to the present time, English composition, and geography. My preliminary examination was completed by a fifth member of the board, asking me concerning zoology, spectrum analysis, and of scientific expeditions to observe the transit of Venus, of the knowledge they expected to gain and the instruments used. To say that I answered all the questions correctly would be presuming too much. The recorder said that I did finely.

"After this followed the regular surgical and medical examination, which was rigid. It was partly written and partly oral and was conducted with a view to finding out what a candidate does not know.

"It is impossible for a candidate to pass a successful examination unless he is considerably better than the average medical student. My examination closed today, and I was told results were satisfactory."

According to the Adjutant General's records, he died at Eagle Pass, Texas, November 17, 1888, aged forty-one.

Dr. D. C. Rowland came to Twin Lakes, Freeborn County, early in the summer of 1872, where he soon established the reputation of being a competent, honorable, and able physician. A card dated July, 1872, says:

"I will treat all diseases to the best of my ability. Have made a special study of diseases of women and children and chronic diseases of long standing. By long experience and strict attention to my profession, I am confident of treating all curable diseases with success. Obstetrical cases treated with care and success."—*Standard,* July, 1872.

"From July 11 to October 29, 1872, he rode twenty-two hundred miles." (*Standard,* November, 1872). This no doubt was on horseback, as in those days trails were few and for the most part impassable for horse-drawn vehicles. If destinations led where passage was impossible for horse and rider, they could both take a little roundabout walk, which no doubt often happened.

Dr. Rowland was an eclectic physician and "in October, 1875, he left for Cincinnati, Ohio, where he attended a course of lectures in that school." (*Standard,* October, 1875).

"Dr. Rowland, who has been home visiting his folks at Battle Creek, Iowa, is making preparations to move his office to that place. Dr. Rowland is a good physician and it is to be regretted that he does not find it to his interests to remain here."—*Enterprise,* January 31, 1884.

He left Twin Lakes in 1884 and located at Sioux City, Iowa. After retiring, he went to Red Bluff, California, where he died.

Dr. M. M. Dodge was born at New Lime, Ashtabula County, Ohio, Oct. 28, 1842, and at the age of fifteen began teaching school. In 1859 he studied medicine with Dr. Porter Key in his native town, and in 1861 entered the Cincinnati Hospital. In the winter of 1863-1864, he attended lectures at Ann Arbor, Michigan. The following spring he moved to Wisconsin, immediately enlisted in the Fortieth Wisconsin Volunteer Infantry, Company D, and was detached as assistant surgeon in the Adams Hospital, upon the regiment's arrival in Memphis. After the close of the war, he located in Chicago; and after the fire in October, 1871, having been burned out, he attended lectures at the Hahnemann Medical College, from which he graduated February 22, 1872. The same year he married Miss Lucy Norton and moved to Lone Rock, Wisconsin. In the spring of 1874 they came to Albert Lea, where Dr. Dodge established an extensive practice. In his newspaper card he announced himself as "College read, of long experience and a homeopath, and therefore would not be materially in competition with the other schools of practice."—*Freeborn County History,* 1880.

The following is a dictation taken during an interview with an old personal friend:

"Dr. Dodge, besides being a successful practitioner, had a colorful personality. He was always well dressed, shoes shined, generally wore kid gloves, and was very neat in his appearance. He was a lover of good horses. I recall a fine bay team of his, well matched, always carefully cleaned, groomed, and well harnessed, hitched to a clean good looking carriage. Sometimes when he received a call, he would come out of his office in a dignified manner, get into his carriage, give the horses the proper signal, and start away in a whirl of speed and dust as though going to a fire. Passers-by were sure to think that something very serious had happened and that the doctor's presence was urgently required. Other doctors might intimate that he might not have any call at all, and was only putting on a little show; but in any event, all knew the doctor was on his way.

"Dr. Dodge was of the generation that believed that whiskey might, on occasion, be used as a beverage. Now and then he would over-indulge, tell some one what he candidly thought about him, and sometimes find himself in justice court charged with assault. He would be fined the customary amount, pay it, and then arise in a Chesterfieldian manner, compliment the justice on his careful observance of the law, apologize to him for causing him any trouble, apologize to the victim, and then make a dignified exit. Apparently those episodes had very little effect on the volume of his practice. . . . I recall a well known citizen of Albert Lea being indisposed and in bed. His wife diagnosed his illness as heart trouble. She got word to Dr. Dodge to come in a hurry. When he arrived, she met him at the door and in a very agitated manner urged him to 'Hurry! hurry! Tom is very ill.' 'What seems to be the matter?' asked the doctor. 'Oh, it is his heart, his heart!' 'Rule that out,' the doctor replied. 'That is impossible; that —*—* fool hasn't any heart.'"

Dr. Dodge spent the winter of 1888-1889 in Chicago, specializing in gynecology. In 1890 he moved to Tacoma, Washington.

Dr. Willis H. Twiford came to Freeborn County and settled in the village of Geneva in 1873. He built a fine home in 1875 and owned adjacent land, which he farmed and on which he later platted a fine addition to the village. He was a kindly gentleman, a very solid general practitioner, and one true to his trust. He was born

May 12, 1821, in Fayette County, Ohio. His mother died when he was seven years old and left a family of ten children. In early life he improved all opportunities offered him for obtaining an education. He attended the academy at Delaware, Ohio, for two terms and later entered the office of Dr. Stanley Skinner, Jr., with whom he read and practiced. He studied medicine for three full years and graduated with the degree of M.D. at the Starling Medical College of Columbus, Ohio, in 1845. In April, 1846, he married Miss Nancy R. Darling, daughter of Jeremiah Darling, Esq., of Madison County, Ohio.

Dr. Twiford practiced for a time at Plain City, Ohio, until August, 1853, when he removed to Union City, Indiana, and remained there until the war in 1861. He joined the Twenty-fifth Indiana Regiment as assistant surgeon and was soon commissioned surgeon. He was in charge of the hospital on the field at the battle of Antietam. He was later appointed by General Hooker as Surgeon-in-Chief of the First Division of the Twelfth Army Corps. He held this commission until July, 1864, when he resigned in consequence of an injury to his spine that resulted in partial paralysis. He came to Minnesota in 1864 and first settled at River Point, in Steele County. Here he was elected to the ninth legislative session of the state in 1866. Dr. Twiford was a Republican and active in politics. He became interested in the projected Duluth and Mankato Railroad, which gave promise of including the village of Geneva, and for several years he was a member of its board of directors. This venture, however, never materialized. After practicing medicine for fifty years, he sold his practice in 1895 and retired and moved to Owatonna, where he died in 1902 at the age of eighty-one.

Dr. W. D. Cole located at Albert Lea in 1873. In his newspaper card he advertised that he was an eclectic physician, a veterinary surgeon, and a druggist.

"Go to Cole's drugstore, where you can buy pure drugs and medicines. Do not ruin your chances of recovery by being drugged with mercurial preparations under the old system, but adopt the only scientific system—the Eclectic. Chronic diseases of long standing a specialty. Consultation free."

In 1879 he moved to Mankato, and in 1883 went to Olmsted County. He was addicted to "the liquid havoc of the oaken stave, and warmed with its deviltry, was arrested and heavily fined for assault in Rochester in November, 1883." (*Enterprise,* November, 1883). He died at Alden and was buried at La Crosse, Wisconsin.

Dr. F. J. Benham, a graduate of the State University of Iowa Medical College, located at Alden in 1873. He came from Cascade, Iowa, and evidently was a well-qualified physician. "He practiced for a while at Alden and the next year returned to Iowa. In December, 1880, he and his wife were lost with the steamer Alpena, which foundered in a storm on Lake Michigan."

(To be continued in the January issue.)

President's Letter

OUR CHALLENGE OF PERSONAL RESPONSIBILITY

The end of the year is a traditional and appropriate time to reflect upon some of the accomplishments which have taken place in your State Association during the past twelve months. I shall touch on these matters only briefly, however, because I believe it is even more important at this time to look knowingly at the problems ahead, to acknowledge frankly and realistically the shortcomings which still beset us, and to determine not only to keep on stating our case but to back up such statements with the kind of day-to-day performance that clearly associates our services with the public interest.

It has been the aim of our Association this year to expand its health education program. I believe the Association has made substantial progress in this direction. And I emphasize again that the credit for this belongs to you as individuals, because good public relations are the cumulative result of sound thinking and conduct by our individual membership. We have attempted to be realistic in our approach to this problem. Information has been sent from the state office to each individual practicing physician; the local county medical society has been encouraged to realize its importance as a fundamental bulwark in our relations with the public; and other medical organizations, including the Woman's Auxiliary, have been familiarized with our objectives.

We can count these definite results: I believe that every member is better informed and realizes the necessity for keeping informed more than ever before. (I am referring not alone to technical medical information, but also to information which helps the medical man have a greater awareness of the current relationship of himself and his profession to the community.) A new interest is evident in the county medical societies, and only a continued improvement in attendance in these society meetings is necessary to further heighten their effectiveness. The Woman's Auxiliary, together with the Public Health Department of the state, has done a magnificent piece of work in "Health Days." The Governor of the state has been most co-operative in all of our activities.

That we have just begun to scratch the surface on many of these activities I am sure most of you will readily acknowledge. Under the leadership of our very capable incoming president there is no question that the approaching year will see even greater efforts along these and other lines. To my way of thinking—and without reasserting all of our specific public relations problems which I have touched on in recent months—one primary question holds the key to whether our Association and private medicine in general will move ahead or retrogress during 1949 (we cannot, of course, stand still). It is this:

Are you prepared and willing to exercise the deed and vigorous individual responsibility which these times call for from medical men?

It is regrettable that some well-meaning persons within the ranks of medicine still refuse to acknowledge that we present-day medical men have fallen heir to peculiar problems or that our profession faces something of a crossroads. These individuals can only be compared with the proverbial ostrich seeking solace from reality by placing his head in the sand. Medicine won a high professional standing through diligent, intellgent work, and more of the same will be required.

The individual responsibility which we exercise in accomplishing this, in turn, will avail us of added resources of courage to do a better job, for courage stems from a rightness and a knowledge that the job you do is successfully meeting every challenge of the new era in which we live. Your Association solicits your continued and wholehearted cooperation, and here, as possibly at no time in the past, you will in turn find the value of our organization from a local, state and national level.

President, Minnesota State Medical Association

PROVISION OF MEDICAL CARE

THE SURPRISING and, to some people, stunning victory of the Democratic Party suggests that renewed efforts will be made to establish some form of compulsory federal sickness insurance resembling the various Murray-Wagner-Dingell Bills submitted to Congress in recent years. Inasmuch as President Truman has given his approval to these bills on previous occasions, there is no reason to think he has changed his philosophy on this subject. Whether he will be able to persuade Congress that State Medicine will be to the benefit of the people is another matter. If we, as physicians, are convinced that placing our profession in the employ of the government will lead to an inferior type of medical care for American citizens, it will behoove us to tell our Representatives in Congress our convictions and to persuade others who are leaders in the community to do likewise.

That medical care is costly, everyone will admit. So is everything else. The doctor's bill is but one cost item and in many cases, compared with the hospital and nursing cost, is a smaller item. Widespread hospital insurance helps to care for the mounting cost of hospitalization, but its benefits and of necessity its rates should be increased to afford more needed protection. Voluntary medical insurance is growing fully as rapidly as was the case with hospital insurance, and the State Medical Associations' insurance, the so-called Blue Shield Plan, provides satisfactory coverage for the low income groups. Every effort should be made to increase their scope. It is true that both the Blue Cross and Blue Shield plans do not include the indigent, but neither do the proposed compulsory federal sickness insurance bills in which wage deduction provides services for only those employed and their families.

It is not difficult to imagine what the practice of medicine would be if anyone could have the services of a physician without cost to the individual. What a heyday it would be for the hypochondriac and what a headache for the profession! The volume of medical work would greatly increase, and the opportunity would arise, depending on the plan adopted, for either needless calls from the doctor or slipshod medical attention. The present incentives for self betterment stimulated by private practice would be largely eliminated, and mediocrity and inefficiency in medical practice would be favored. We venture to predict that the better doctors in private practice would not participate in State Medicine.

We have called attention before to the prospect of medical care being provided for a large and larger segment of our population—the veterans. The Veterans Administration has authority to build an *adequate* number of hospitals. The present plan is to provide 300,000 beds at a cost upwards of one billion dollars. The Bureau now has more beds than it can staff with doctors and nurses. Veterans who declare themselves financially unable to procure adequate medical care are admitted to the Veterans Hospitals for non-service-connected disabilities, and according to reports from the Veterans Administration more than three-fourths of their hospital beds are occupied by veterans with non-service-connected medical and surgical conditions. It is obvious that the law is not strictly enforced as to indigency. If the veterans in the future demand medical care for their families on the same basis that they themselves are receiving it, only the lack of doctors and nurses to man the hospitals is likely to prevent an extension of tax-supported medical care to an additional thirty million or more of our people. The Veterans hospital building plan, it is said, is running into unexpected and undesirable competition with the hospital building program of the Hill-Burton Act. In some instances, the two construction plans are operating in the same community. We can see the danger of the Veterans Administration being left with large hospitals, unoccupied, because of lack of personnel. We have a faint recollection of a large orthopedic hospital having been built by the Veterans Administration, after World War I, somewhere in

the southwestern desert, which had to be abandoned because there was no orthopedist available. A hospital, without doctors and nurses, irrespective of its location, is useless.

FUTURE DEFENSE OF MEDICAL PRACTICE

SINCE November 2, many inquiries have come from over the State as to the future plans of the National Physicians Committee.

The doctors of Minnesota have responded most generously to the support of the NPC during the past year, donating more than in any previous year. With very little solicitation they have donated more than $15,000.00.

Since November 2, we have all been somewhat stunned. We are not quite sure what we can do to head off political control of medicine. As Congressman Harness has shown, the present administration has spent more than $70 million and employed 3,000 government employes to convince the public that they want compulsory health insurance.

Ewing's ten-year program for the political control of medicine is something that should make every practitioner of medicine stop to think just what we can do for the protection of the profession. We must admit this report of Ewing's is very cleverly camouflaged. He has painted a very clever picture of the future of medicine under his plan. One who has not followed the development of this plan is very likely to overlook the evils which he has purposely failed to mention.

Many doctors still feel that the American Medical Association should be capable of forestalling such a disaster as this plan would institute. It is very plainly impossible for a scientific body, such as the AMA, to meet the trickery and political maneuvers of the politicians who are promoting this plan.

Just how much the NPC will be able to accomplish in our behalf is impossible for any one to say.

The officers and Board of Trustees of the AMA feel that the NPC is at least an important factor in combating the false propaganda that these politicians are endeavoring to present to the public. We are assured that the NPC will not do anything that does not meet with the approval of the AMA.

J. M. H.

CHRISTMAS SEALS

IT IS mainly to the laboratory research work that we must look for the solution of many of the yet unsolved problems of tuberculosis, and for advancement in our methods of prevention and treatment."

This statement made in 1904 by Edward Livingston Trudeau, first president of the National Tuberculosis Association, is still true, as is shown by the emphasis placed today on research work.

The National Tuberculosis Association, in the present Christmas Seal sale, is making a plea for increased funds needed for research work.

Five per cent of the funds raised goes to the National Tuberculosis Association for its research and other work, while 95 per cent remains in Minnesota to finance specific activities in each county and the state-wide program.

In connection with the present Christmas Seal campaign, it is interesting to trace some of the developments through research in the field of tuberculosis.

The discovery of the tubercle bacillus by Robert Koch in 1882 was the first blow at the deadly enemy. By proving that this bacillus was the cause of tuberculosis, Koch revealed that tuberculosis was a communicable disease which could be prevented.

A few years later the discovery of the x-ray by the physicist, William Conrad Roentgen, led to the development of the photofluorographic units which have been of inestimable aid to the physician in diagnosing tuberculosis.

In our own day, the discovery of streptomycin by Selman A. Wakman has encouraged scientists in the belief that a specific drug for tuberculosis may be found.

Despite this progress, tuberculosis still presents many baffling problems to the scientist. One of the most pressing questions at present is: What are the elements essential to the life of the tubercle bacillus?

Professor Rudolph J. Anderson of Yale University, who is making a chemical analysis of the tubercle bacillus, under a grant from the National Tuberculosis Association, was awarded the 1948 Trudeau medal by the National Tuberculosis Association in recognition of his work.

In a recent article in the *Bulletin* of the National Tuberculosis Association, Corwin Hinshaw, M.D., president of the American Trudeau So-

ciety, summarized the present-day knowledge as follows:

"Of the antibacterial drugs in tuberculosis, streptomycin is the only sufficiently tested and adequately effective preparation that can be recommended. It was not the first chemical remedy to be developed and I do not believe that it is the ultimate drug despite its pre-eminence at this time. New drugs must be tested exhaustively in the laboratory.

"Progress may be slow because there is a great gap between the guinea pig and the patient with tuberculosis; however, the gap between the culture tube and the experimentally infected guinea pig is still broader. To traverse these barriers will entail vast expenditures of patience, energy and money. We must recruit more scientists, technicians and dollars to engage in this worthy cause.

"There has never been a time when the word "control" of tuberculosis could be defined so precisely; when your job and mine were so clearly evident. We now think of tuberculosis in terms of persons; how to persuade them to make use of new and available diagnostic facilities, how to give them the benefit of the new advances in surgery and drugs.

"We are engaged in a struggle against an enemy, nothing abstract or intangible, but a living, growing, breathing being. The size of this enemy is microscopic, but numerally this bacillus is a very great enemy, clever and sinister in his attack. Great battles are being won against this enemy, but our efforts must be through direct methods to find where our enemy is and how to attack him directly when found. Now we seek and find this enemy by health education and mass radiography. We attack him with greatly improved weapons of therapy.

"The inspired leadership of voluntary organizations was never needed more acutely than it is now."

THE KENNY INSTITUTE

The Kenny Institute, founded in December, 1942, at the Lymanhurst hospital building in Minneapolis for the care of poliomyelitis patients has been the subject of controversy in medical as well as lay circles.

With the appointment of Dr. E. J. Huenekens, a well-known pediatrician of Minneapolis as chief of staff of the Institute last August; the addition of Dr. Miland E. Knapp as chief of physical medicine in charge of treatment and training of physiotherapists; also of Dr. John F. Pohl as consulting orthopedic surgeon, Dr. S. R. Seljeskog, and others, the Institute is assured of first-class professional supervision.

Sister Kenny, after whom the Institute is named and whose contribution to the treatment of poliomyelitis is recognized, will remain active with the Institute.

Sister Kenny recently made the following statement which appeared in the press:

"The Kenny institute is now under the direct supervision of members of the three departments of medicine—that is, pediatrics, physical medicine and orthopedics.

"These gentlemen have honored me by asking me to remain as consultant and teacher. This is a goal I have been working years for and at last achieved.

"I quite agree with the procedures of members of the medical profession for their caution in not embracing new ideas that may from time to time be presented, including my own, until they are satisfied they are effective. That is wisdom, and proves the public can confidently put their trust in their activities."

Dr. E. J. Huenekens adds the following comment:

"As background to the above statement of Sister Kenny, I wish to say that three months ago I accepted the position of Chief of Staff of the Kenny Institute because I firmly believe in the value of her treatment. There were two conditions to my acceptance: first, that I be given full responsibility for the medical direction of the hospital; and, second, that Dr. Miland E. Knapp have complete charge of the physical medicine aspects of the treatment with sole authority over the technicians, as he now has at the University Hospital and Sheltering Arms. These conditions have been fully met.

"A further reason for my taking over was to establish such relations with the University that the facilities of the Institute would be open to its staff for research and evaluation of the treatment. We are now in the process of working this out.

"Most important of all, we hope to do away with the antagonism that exists between Sister Kenny and the medical profession, which has caused both to be misunderstood by the public. If these misunderstandings can be resolved, physicians will be able to judge the Kenny method objectively; and, to that end, they will be welcomed at the Institute in the future to observe for themselves the treatment and its results."

SELECTIVE SERVICE AND THE MEDICAL PROFESSION

The induction into the Army of draftees began in October, 1948. The method differs from former procedures in that now the men are given their pre-induction examinations, not at Army installations but at their nearest Army or Air Force Recruiting Main Stations by civilian physicians. These stations are located at Bemidji, Duluth, Mankato, Minneapolis, St. Cloud, Willmar, and Winona.

The pre-induction examination consists of a mental test and a physical examination.

The mental test is an intelligence test and requires a rating of 70 or over for acceptance. From past Army experience with this test, 19 per cent have failed to pass, 19 per cent rated 70 to 89, 30 per cent 90 to 109, 26 per cent 110 to 129, and 6 per cent 130 up. From the Army's experience those rating 90 to 109 furnish the best soldier material. From those rating above 110 the Army selects those who qualify as leaders to be non-commissioned officers and its officer material.

The physical examination is designed to determine the individual's functional ability to perform military duty. This includes a test of his physical stamina, strength in arms and legs, hearing, vision, and neuropsychiatric make-up. He must pass all parts of the physical examination. Serology and chest x-ray examinations are also done.

The examinations are made by civilian doctors with

MEDICAL ECONOMICS

Edited by the Committee on Medical Economics
of the
Minnesota State Medical Association
George Earl, M.D., Chairman

"ELECTION" IS THE WORD—WHAT IS THE TRANSLATION?

The people have spoken, in the way that a democracy speaks—by ballot. The word they've spoken is Truman, but what the word means, what are the nuances, the implications, the final result for medicine is yet to be seen. Fortunately, democracy is a game where everybody plays; nobody sits on the bench except by choice. Let's see to it that medicine has a strong team so that the final score will be in favor of private enterprise.

NORTH CENTRAL CONFERENCE STUDIES VARIETY OF PROBLEMS

Nearly 100 physicians from the six-state north central area exchanged information and opinions November 7, at the Hotel Radisson, on problems of mutual concern—the national program of Blue Cross and Blue Shield, Co-operatives and the practice of medicine, medicine in the next medical emergency, standards for prepaid medical care, the nursing shortage, the general practitioner and expansion of State Association programs.

The session, annual for the North Central Medical Conference, began with an address by A. W. Adson of Rochester, president of the conference. First of the discussion groups was that of Blue Cross and Blue Shield, led by James R. McVay, Kansas City, Missouri, chairman of the AMA's Council on Medical Service. Discussants were F. L. Feierabend, Kansas City, Missouri, and H. R. Brown, Watertown, South Dakota. Much interest and participation from the floor was provoked by the question of the proposed Blue Cross-Blue Shield association and formation of a national insurance company. Later, the Conference went on record as (1) approving a proposed resolution which would require that all Blue Shield Commissioners be practicing physicians and (2) commending the Council on Medical Service and the Board of Trustees of the American Medical association on their studies and analyses of the two Blue Cross-Blue Shield plans of action.

Mr. Crownhart, Madison, Wisconsin, secretary of the State Medical Society of Wisconsin, forecast six basic problems resulting from the impact of corporations on medical practices: "Are the services for the covered person going to be available when needed? Is there assurance that such ancillary procedures as are made available will measure up to the proper public health standards? Is the medical and surgical judgment of the attending physician unshackled? Will the plan make available properly qualified physicians for the services promised? If hospitalization benefits are included, are they adequate and within proper levels? Is quality maintained through free choice?"

Discussants in this section were W. A. Wright of Williston, North Dakota, and R. F. Erickson of Minneapolis.

Dinner was served in the Italian room and followed by two brief addresses: Gunnar Gunderson, LaCrosse, Wisconsin, outlined responsibilities of the American Medical association Board of Trustees, of which he is a member; and Thomas A. Hendricks, Chicago, Illinois, secretary of the AMA Council on Medical Service, listed "ten commandments for prepaid medical care," voicing his belief that the "quantity and quality" of medical services would be less, the cost "tremendously" more in any form of socialized medicine.

Howard K. Gray, Rochester, member of the AMA Committee on Nursing Problems, reviewed the suggestions formulated by the committee in seeking an answer to the nursing shortage question: attempt to bring nurses out of retirement, fit as many practical nurses into the picture as possible, train on the job attendants, see to it that work improperly assigned to nurses is given to others, stimulate the recruitment of nurses,

plan a grade of nurses below the present day professional nurse to do bedside nursing under the professional nurse's supervision, attempt to include nurses under the social security act, investigate retirement plans for nurses, consider the possibility of tying in nursing costs with the voluntary prepaid hospital and medical care plans.

R. G. Mayer, Aberdeen, South Dakota, and H. E. Stroy of Osceola, Iowa, assisted Dr. Gray in developing the discussion.

Revamping the course of instruction for general practitioners was among the suggestions brought forward by Mac F. Cahal, Kansas City, Missouri, secretary of the American Academy of General Practice, in his discussion of "The General Practitioner." With added skills and self-confidence, the GP could care for more of his difficult cases instead of referring them to specialists, he pointed out, quoting from a recent survey by a group of eastern specialists who found that more than 800 out of 1,000 cases referred to them by general practitioners could have been or should have been handled by the general practitioner himself.

Roy Fouts, Omaha, Nebraska, and N. G. Alcock, Iowa City, Iowa, served with Mr. Cahal on this discussion team.

Advocating economical use of American medical manpower in preparing for national defense, Harold R. Hennessy, Chicago, secretary of the AMA Council on National Emergency Medical Service, emphasized the need for medical representatives in the higher circles of governmental planning. ". . . America is losing her provincialism," he declared. "In its place there is being created a world consciousness and a sense of world responsibility and leadership, all of which means that American medicine, as a powerful and determining force, rightfully deserves representation in all high level planning assignments. Thus, in the expanding scope of national defense which strongly suggests the size, shape and scale of things to come, we can, through joint efforts, not only assure our national security, but we may also hope to prevent World War III."

Expanding State Association programs to meet present day sociological, political and economic threats was advocated by Floyd L. Rogers, Lincoln, Nebraska, chairman of the Nebraska State Medical Association's planning committee, and his discussants, A. E. Cardle, Minneapolis, and A. D. McCannel, Minot, North Dakota.

Dr. Rogers described Nebraska's plans as a "broadening and correlation of our activities . . . to bring about a maximum in completeness, efficiency and quality of medical service, curative and preventive, with emphasis on the creation of a better understanding between the public and the medical profession."

"In order to accomplish such a broad program, he continued, "we physicians must have a definite change of attitude. We must change from an attitude of stubborn resistance or indifference to one of aggressive and constructive leadership. We must admit that we have shortcomings, and some of these are serious. We must understand that the public realizes these shortcomings more than we, that they suffer because of them, and that they want and will have something done about them. It is for us to look sharply for our own weaknesses and to promptly and aggressively set out to correct them."

Nebraska's program was outlined in seven major points: public health, preventive medicine and health education; self-disciplinary measures; Nebraska Medical Foundation; continuous scientific educational program for the medical profession; Nebraska Medical Service; uniform fee schedule for governmental agencies; continuous sociological research program.

GOVERNOR'S CONFERENCE MAKES HEALTH SUGGESTIONS

The health panel of the Governor's State Conference on Youth, set to work October 18 to recommend conservation measures for the health of the state's estimated 1,000,000 children and youth. "The well being of these people constitutes the most valuable resource of the State," the panel agreed. "The future status of this well-being is dependent in large measure on the health care and protection and education given to the children and young people. Their health is of great concern to the State."

Stressing preventive care, the panel submitted a list of recommendations to the conference which included: extension of qualified prenatal and maternity medical care to all mothers to assure every child the opportunity of being born sound and healthy; medical supervision of children and youth administered through the medium of periodical health appraisals for guidance of growth and development, supervision of nutrition, detection and correction of physical defects and for

the detection, prevention and treatment of emotional and mental disturbances.

The panel favored prevention of dental disease and provision of dental care for pre-school and school children, prevention and control of preventable and communicable diseases and a sanitary environment for each child.

Following the enumerated recommendations, the panel took up the cudgels for local health unit legislation, pointing out that "organization for public health service is deficient in Minnesota, apparent from a brief review of the existing facilities."

"Minnesota has a strong State Health Department which gives a limited direct service from the central office and through eight branch offices. The unit of government which is needed is the full-time local health department which has been developed and recommended for universal adoption by the public health and medical authorities of this country."

Dr. Viktor O. Wilson, city health officer at Rochester and former chief of the special services section, Minnesota State Department of Health, served as chairman of the Health panel.

Other divisions of the conference were: church, community organization and co-ordination, detention and protective care, employment and youth welfare, home and family, housing and youth welfare, institutional handling, juvenile court laws, juvenile justice, law enforcement, recreation and youth participation, rural youth, school and teacher, social services, treatment facilities.

A report of the two-day Conference findings will be available in published form shortly.

MINNESOTA TWELFTH IN NUMBER OF PHYSICIANS

Minnesota, with 4,263 living physicians, ranks twelfth in the nation in number of physicians, according to a recent survey by Frank G. Dickinson, director of the AMA Bureau of Medical Economic Research. States with more doctors are: New York, 30,970; California, 16,069; Pennsylvania, 14,633; Illinois, 13,307; Ohio, 10,091; Massachusetts, 9,102; Texas, 7,621; Michigan, 7,127; New Jersey, 6,585; Indiana, 4,396; Missouri, 5,352.

The Minnesota total is 2.24 per cent of the 199,755 physicians in the entire United States.

Commenting on his study, Dr. Dickinson said: "At this stage of our operations, one important statistical fact emerges. The (approximate) number of living physicians in the United States is now *17 per cent* greater than the 170,163 shown in the 1940 AMA Directory; the population of the United States has increased only *12 per cent* since 1940."

When the tabulation is completed, Dr. Dickinson expects to have a breakdown of the total figures, locating the physicians in such groups as: practicing, retired, employed by federal, state and local health agencies.

Marshall Man Pleads Guilty to Illegal Practice of Massage

Re. State of Minnesota vs. Frank Sprader

On November 15, 1948, Frank Sprader, forty-eight years of age, Marshall, Minnesota, entered a plea of guilty in the District Court of Lyon County, Minnesota, to an information charging him with the crime of practicing massage without a license. Following a statement of the facts to the Court, Sprader was sentenced by the Hon. A. H. Enersen, Judge of the District Court, to a term of three months in the Lyon County jail. The sentence was suspended for a period of one year on condition the defendant pay the Court costs and obey all the laws of the State of Minnesota, including the massage law. Sprader must also report to the County Attorney of Lyon County, once every two months during his probation.

Sprader stated to the Court that he was born at Manitowoc, Wisconsin, in 1900 and that he moved to Ivanhoe, Minnesota, in 1908. Sprader stated that he is married and has eight children ranging from less than one year to seventeen years. Sprader admitted that he had been practicing massage at Marshall, Minnesota, since January, 1947. He stated he averaged about four patients per day and charged $2.00 per treatment. Sprader had in his possession at the time of his arrest a massage diploma from the College of Swedish Massage, Chicago, Illinois. Sprader admitted that he did not attend the school but took a correspondence course. The diploma is dated October 30, 1945, and reads as follows:

"Frank S. Sprader has completed a prescribed course in Health Culture and has passed a creditable examination in the art of scientific Swedish Massage, Medical Gymnastics, Dietetics, Hydro Therapy, Swedish Face and Scalp Treatment, Hygiene and the underlying principles of anatomy and physiology."

Sprader stated to the Court that he ceased practicing massage at the time of his arrest in June. Upon being asked by Judge Enersen as to how he was making his living at the present time, Sprader replied that he was doing carpenter work and also paper hanging. The Minnesota State Board of Medical Examiners wishes to acknowledge the co-operation received in this case from C. J. Donnelly, County Attorney of Lyon County, and also Sheriff Roland Rans and Deputy Sheriff Knute Bergman of Lyon County.

BRITISH MEDICAL TRAGEDY

The tragedy which has befallen the British medical profession under socialization offers a clear lesson on the dangers of government medicine to the United States, Warren H. Cole, M.D., a leading surgeon and a faculty member at the University of Illinois College of Medicine said in an address before the Employes' Benefit Association in Chicago, November 10, 1948.

Dr. Cole recently returned from a three-month stay in England as a member of an American Department of State medical mission. He made a thorough study of the effect of the new National Health Service Act during his work there.

"Any advantage that might be put forward to justify the operation of medical service by government is immediately neutralized by the fact that the quality of medical care promptly nosedives," Dr. Cole said. "There are several reasons why that happens."

"First, the number of office visits increases tremendously. That has already happened in England since the NHSA went into effect last July. Since doctors are already overwhelmed by present demands on their time, they obviously do not have time to examine all patients thoroughly. Unfortunately, the patient who makes the loudest complaint will be most likely to receive attention.

"Again, the doctor has no incentive to do good work. There is no financial reward in sight, and the stimulus of competition is eliminated. Even Russia realizes the value of competition in medicine.

"A third factor is that, when patients, thinking they are not paying for medical care, crowd the doctor's time with troubles they would otherwise disregard, the doctor becomes disgusted with practice and becomes lax in his vigilance for serious disease.

"Fourth, most doctors are unhappy and dissatisfied with socialized medicine, with resultant deterioration in their efforts. It is impossible to get good service from such doctors."

Another important and tragic result of socialization, Dr. Cole said, is the destruction of the doctor-patient relationship. Since the doctor has no incentive and is too busy anyway, he will not take the time to talk to a patient about his problems, especially those emotional and mental intangibles which affect health, but cannot be quickly identified as physical symptoms can.

Under government medicine, too, Dr. Cole continued, the patient in England has little choice of doctors. He can only ask for a specific doctor if that doctor's panel is not full.

Government's confiscation of hospitals in Britain destroys community interest in the institution, Dr. Cole said, while the increased demand for hospital beds by undeserving patients makes it more difficult for really sick persons to be accepted as patients.

Government medicine, aside from its evil effects, is not necessary in the United States, Dr. Cole said, though some form of compulsory medicine is part of the program of President Truman.

SELECTIVE SERVICE AND THE MEDICAL PROFESSION

(Continued from Page 1349)

the help of Army medical technicians. The Army has established a standard price for the services of the civilian doctor employed which consists of a maximum of $25.00 a day, or if more economical for the Army, $5.00 for a single examination, plus $2.00 for each additional examination on the same day. Fees for chest x-rays with interpretations are $5.00; without interpretation, $3.00. Interpretation of radiograph by a radiologist is paid for at the same rate of $25.00 a day, or $2.00 per film.

Should evidence of need for an examination by a psychiatrist become evident in the physical examination, a special neuropsychiatric examination is made. Psychiatrists are allowed $25.00 a day.

The Minnesota State Department of Health makes the serology examination.

Superficial physical inspections are made at the time of induction, which is never less than twenty-one days after the pre-induction examination. These inspections are also made by civilian physicians who receive compensation if not over $25.00 per day, or at the rate of $1.00 per man.

It is the desire of the United States Government to utilize civilian doctors to the fullest extent in the examination of inductees, in order to keep at a minimum the need for doctors in the armed forces. Doctors and qualified psychiatrists are urged to offer their services to the Recruiting Centers.

In Memoriam

JENNINGS CRAWFORD LITZENBERG

An Appreciation

With the death of Dr. Jennings Crawford Litzenberg on August 15 of this year, one of the most illustrious careers in the history of Minnesota came to an end. A career distinguished by a long tenure of forceful teaching, eminent through service as a practicing physician in his community, and marked for its prominence in local, state, and national medical societies.

Dr. Litzenberg was born in Waubeek, Iowa, on April 6, 1870. When he was six years old, his father moved the family to Anamosa, Iowa, because the larger community promised greater opportunities in the practice of law. He was a fifth generation American on both his paternal and maternal sides. Both of his great great grandfathers fought in the Colonial Army during the American Revolution. His paternal ancestors came from Hanover, Germany, in 1700, and those from the maternal side (Crawford) arrived from Scotland, in 1730. In the succession of generations to follow, his family tree acquired Scotch Irish, English and Welsh graftings, so that with a characteristic witticism he could describe himself as, "A product of the American melting pot, in animal breeding parlance, a mongrel." Following the death of his father in 1890, at which time he had completed his primary education, Dr. Litzenberg and his mother moved to Minneapolis, Minnesota. In the autumn of that year he enrolled in the University of Minnesota, beginning a connection which lasted actively until 1938, when he retired from the Chair of Professor and Chief of the Department of Obstetrics and Gynecology, though he remained as Professor Emeritus until his death.

Dr. Litzenberg's intention upon entering the University was to follow his father's profession of law. However, in his second year, probably through the influence of three physician uncles, he switched from the classical course to the scientific, as a prerequisite for the study of medicine.

To envisage Hon. J. C. Litzenberg in the role of attorney and the station which his vigorous zeal, forthrightness and amity would have earned him, makes an interesting and fascinating conjecture.

After his graduation from the scientific course in 1894, insufficient funds prevented him from entering the Medical School immediately. He obtained the position of Superintendent of Schools in St. Louis Park, a suburb of Minneapolis, where he spent the next year. Then, through a fortunate turn of affairs, he was appointed the Educational Director of the Evening Schools of the Minneapolis Y.M.C.A., with a salary sufficient to provide for his matriculation in the Medical School. He retained this post for three years, during the last of which he acted as interim General Secretary. At the Y.M.C.A. he met the late Dr. L. J. Cooke, the Physical Director, who was shortly to be chosen by the Board of Regents as the Director of the University of Minnesota Gymnasium.

Upon accepting his appointment Dr. Cooke chose Dr. Litzenberg as an assistant, a position that he occupied for the next ten years. Such a background undoubtedly was the source of an interest in young men, athletics, and teaching, that he so vitally retained until the end: an interest, which was commensurate in vigor with the tremendous expansion of the University and the community. No man in the history of the Institution had such a prolonged prestige as was his. "Minnesota! Hail to Thee!" intoned in the beauty and the solemnity of a pipe organ, at his last rites, was the symbol of his life, so deeply and widely dedicated.

After receiving his medical degree in 1899, Dr. Litzenberg spent the next year as an intern in the Minneapolis General Hospital. It can be pointed out that considering the period and the locality, his formal education was far beyond the usual and accepted standard. At that time there were no required premedical courses. Nearly all of the students entered the Medical School directly from high school.

In 1900, he opened an office in Minneapolis where "I practiced more Economy than Medicine for a couple of years." At about this time he made his first formal appearance as a teacher in the Medical School as an assistant in Ophthalmology and Otology. He did not reveal what turned his interest, but in 1902 he became a Clinical Instructor in Obstetrics, the field in which he ever after remained pre-eminent.

In 1902, he married Elizabeth Fisher, of the Class of 1898, University of Minnesota. She bore him two children: Karl, now a Professor of English at the University of Michigan, and Avis, now Mrs. Chauncey G. Chase, residing in Minneapolis. This son and daughter have in turn become the parents of five grandchildren concerning whom, contrary to his usual reserve, there was no concealment of his pride. Photographs were reasonably available at all times with appropriate explanations as to each youngster's extraordinary characteristics.

"Liz" and "Litz" quickly became the emblem of the completely happy marriage. For his ideals she willingly sacrificed the added comforts that a greater continuity of practice could have brought to their home, and in return he eagerly embraced her ideals in the spiritual realm of church, music, and the home.

In 1907, after five years of service as an instructor

in obstetrics, Dr. Litzenberg was promoted to the rank of Assistant Professor. During this period, he and Mrs. Litzenberg became aware that further preparation was needed in order to aid the advancement of thinking in obstetrics and gynecology in the community. Consequently, in 1909, accompanied by their children, they departed for Vienna, where he studied under the great Dr. Schauta for two years, the latter of which was spent working intensively as a voluntary assistant. Upon his return to Minneapolis and the University he was made an Associate Professor in Obstetrics and Gynecology, an appointment that marked the first recognition by the University Medical School of the intimate relationship of these two subjects, and from this time the two have been taught together.

In 1913, Dr. George Edgar Vincent, the President of the University of Minnesota, who later became the Head of the Rockefeller Institute, shook the Medical School to its foundation by calling for the resignation of the entire faculty of the Medical School. He had a real conviction that the medical faculty was too large, contained too many general practitioners and too few trained teachers and investigators. In the subsequent reorganization of the Medical Faculty under Dean Westbrook, Dr. Litzenberg was invited to become the Professor and Chief of the Department of Obstetrics and Gynecology.

The appointment pleased him, but he always declared that it astonished him. However, where was there another with the foresight and the fortitude to prepare so diligently for an inevitable development? His ancestors first came to Pennsylvania, from whence they moved into Ohio, later advancing into Iowa. Was he through his heritage of expansion and pioneering not made sensitive to the potentialities of his environment? A community that during his lifetime increased tremendously in population and developed astoundingly in progress and culture.

Following the acceptance of his appointment he almost immediately returned to Europe for another year of study under Dr. Schauta in Vienna, and Dr. Bumm in Berlin. In his reminiscences he jokingly contrasted his first stay in Europe as a student with his later visit as a Professor—Hoch Professor—a status which required formal clothes, a silk hat and the appendage of a gold-headed cane.

Following his second return from Europe, Dr. Litzenberg undertook at once his teaching duties and the rebuilding of his private practice. At this time the Medical School of the University of Minnesota was, except for the University of Iowa, in the unique position of having the only complete medical course in what was then known as the Northwest States; a station which made it the center of influence not only in Minnesoa, but in the Dakotas, Montana, and considerable portions of Iowa and Wisconsin.

In 1927, when Dr. Litzenberg had reached the height of his career, an eminence which was shared mutually in the tradition of Christian marriage, Elizabeth Litzenberg died. To him this was nearly a catastrophic event. But, after the first shock, in which everything in life seemed to be gone, his measure of a man was exhibited. To their ideal, self was subjugated, and he strove alone toward their mutual goal as a living monument to honor the one who had meant the most to him.

His enthusiasm, force and clarity soon made Dr. Litzenberg one of the most sought-after medical speakers in this large area. In spite of the demands of his private practice and the duties of his formal teaching obligations, he accepted the invitations with remarkable buoyancy. To most men, the activities of practice, teaching, and speaking would have been sufficient to completely fill their lives, but to him it was not enough. He energetically undertook and accomplished creditable researches. To mention only some of them—he was the first to study the relationship between hypothyroidism and fertility; he made classical contributions to the understanding of tubal pregnancy; he interested himself in the problem of tuberculosis during pregnancy in his capacity of obstetrical consultant to the Glen Lake Sanatorium; and he studied the leukocytes in pregnancy. His bibliography, while not as large as those of some of his contemporaries, contained a quality of writing which was meditative, conservative, precise, forceful, and, on occasions, clairvoyant. His last major work was the volume, "Synopsis of Obstetrics," C. V. Mosby and Co., which he published in 1940 and which was re-edited in 1943.

It was not long before Dr. Litzenberg became the most prominent private practitioner in Minneapolis. He was devoted to his patients and, in turn, he was held in reverence by them. Simultaneously, he became a favorite consultant. To those with whom he consulted he was considerate and tactful. He was held in esteem as a consultant because of the respect he constantly exhibited for his conferee.

During World War I there were instances when he took over the care of the patient of a colleague who had entered the armed services. Upon completion of the case the fee was sent to the wife of the colleague. The occasions on which he assumed or shared the responsibility of the care of the relative of a colleague are innumerable. In 1920, he joined with a group of distinguished associates, all of whom held high positions on the teaching staff of the University Medical School, to form the Nicollet Clinic, an organization in which he remained active until shortly before his death. During World War II he sacrificed a life of semi-retirement to actively conduct the work of the Department of Obstetrics and Gynecology in the Clinic.

It was never obvious which gave Dr. Litzenberg the more gratification, his life as a practitioner with its multiple and varied contacts, or the activities of his academic life. In perspective, in his era when few if any academic-clinical careers existed, were they meant to be separated? Rather, was it not an integrated whole? Was the effect and force of his teaching not conditioned by an appreciation of the problems of the private practitioner gained through his own experience, and conversely, was his capability as a practitioner not enhanced by the stimulation he received through teaching and investigation? In these questions may be the answer to the conflict of ideas in the medical educational methods of today. Is the teaching of medicine

to be removed farther and farther from its practice through augmenting every department with more solely academic careers in which the present clinical academician ostensibly has his greatest interest, or are the teaching and practice of medicine to be component parts of a well-rounded whole?

Dr. Litzenberg's description of the four phases of a trend in medicine may be applicable. "First, there is the beginning or discovery of an idea. Secondly comes the phase of exploitation of the idea. Thirdly, there is a recession from the inevitable overexploitation of the idea, and finally there is the achievement of balance." May his life not represent the achievement of balance in medical education, however premature it was to the present time when many think that clinical-academic careers are overemphasized?

At the time Dr. Litzenberg ascended to the chair of obstetrics and gynecology, teaching was entirely for the benefit of the undergraduates, nearly all of whom expected to serve as practitioners in those parts of the community which the Medical School influenced. There were no residents. Internships were not a necessary requirement for the degree of M.D. until as late as 1920. Graduate study was undertaken almost entirely in Europe, especially Germany. Soon after its reorganization in 1913 the Medical School of Minnesota developed and adopted a system of Teaching Fellowships in order that graduate study in the various fields of medicine and surgery would be available in this country. Graduate students were required to take didactic courses; to perform supervised clinical work; to participate in teaching; and, in the end, to present a research thesis, the satisfactory completion of which led to the conferment of a Ph.D. degree. This was an innovation in medical graduate study in America and in its development Dr. Litzenberg played no small part. About a dozen men received their training in obstetrics and gynecology through this system while he occupied the chair. Of these, some have extended the impact of his teaching force as formal teachers in distant places; but the others have remained as specialist practitioners, teaching more indirectly through example and consultation.

The reduction in the maternal mortality rate may be the best expression of Dr. Litzenberg's strong influence in this community. At the time he accepted the chair of obstetrics and gynecology, the maternal mortality rate in Minnesota, although one of the lowest in the country, was almost 7 per 1000 live births. From here on there was an almost yearly decline in this mortality rate. In 1930 a marked diminution of the maternal mortality rate was noted, not only in Minnesota but in the adjacent states. That the influence of his powerful teaching was largely responsible for the decline is unquestionable, because it is estimated that by 1930, about one half of the practitioners in this area had been his students. Their handling of obstetrical problems must be considered as one of the major factors in this sharp lowering of the maternal mortality rate. The phenomenon has continued until Minnesota, in 1947, can boast of a record of 0.6 maternal deaths per 1000 live births, the lowest ever recorded in the country, if not the world. Although there are many other elements concerned with the lowering of maternal mortality rates, the effect on it by Dr. Litzenberg as an individual was made real through his medium of advanced training; by his cogent undergraduate teaching; through the instruction he gave as an indefatigable medical speaker; and by his ready willingness to aid a colleague.

While at first he took pride in the declining maternal mortality rates, he later became sensitive to the commendation given him for it. He was constrained to write: "Those interested in saving mothers said that the first thing to be done was to improve obstetric teaching. I gave my teaching life to this problem. Good teaching, however, was not the only factor. My staff was a unit in all-out endeavor to turn out young doctors constantly conscious of the possibility of saving mothers. I have been given too much personal credit for the improved teaching of obstetrics and gynecology in our Medical School. My staff deserves most of the credit, for all members were in accord in a determined effort to improve the teaching."

No more need be mentioned about Dr. Litzenberg's influence in this community except that it quickly drew national notice. In 1915 he was made a member of the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons, an organization that he served as president in 1933-34. In 1916 he was elected a Fellow of the American Gynecological Society. Twenty-five years later he was agreeably surprised by his election to this society's presidency. In the preceding year the Central Association of Obstetricians and Gynecologists saw fit to honor him by electing him its president. In 1927 he served as the chairman of the Section of Obstetrics and Gynecology in the American Medical Association.

In 1920 he was chosen as a member of a small committee of obstetricians and gynecologists to consider the establishment of an American Board of Obstetrics and Gynecology. This was prompted by a growing agitation in the medical profession, as a whole, for some method to identify the trained specialist, because the increase in the number of psuedospecialists who professed specialization not only in one field but in multiple fields had become alarming. In 1930, after ten years of careful study and investigation, this committee established the American Board of Obstetrics and Gynecology, one of the first of the various examining boards to come into existence. Dr. Litzenberg was elected to the board of nine as one of the three members from the American Gynecological Society, a post he retained until his resignation, in 1940.

Few men in the history of obstetrics and gynecology in this country have achieved such wide distinction or have been so signally honored by their confreres. He was truly our "giant of the North."

The attitude of those in his immediate community was shown by his election to the presidency of the Hennepin County Medical Society in 1918, and to the presidency of the Minnesota Academy of Medicine in 1932. In 1937, he was elected to the presidency of the Minnesota Obstetrical and Gynecological Society. The satisfaction he experienced from these choices was

as poignant as when he was honored by the national societies, and is best expressed in his following words, "I have prized these honors because they came from my home societies where the members knew my faults."

is Dr. Olga Hansen until six o'clock P.M. when she becomes Mrs. Litzenberg." Before long they were known simply as Olga and Litz. They shared their love and esteem with the families and friends of each,

UNIVERSITY OF MINNESOTA

TO

JENNINGS CRAWFORD LITZENBERG

IN RECOGNITION OF YOUR LONG AND DISTINGUISHED SERVICE TO THE UNIVERSITY OF MINNESOTA AND TO THE STATE, THE SENATE OF THE UNIVERSITY, THE PRESIDENT AND THE BOARD OF REGENTS PRESENT THIS CERTIFICATE AND EXPRESS THEIR GRATITUDE, ESTEEM AND AFFECTION YOUR NAME IS ALREADY ON THE ROLL OF HONOR OF THOSE WHO AS TEACHERS AND ADMINISTRATORS HAVE CONTRIBUTED TO THE DEVELOPMENT OF A GREAT UNIVERSITY HAVE ENRICHED THE LIVES OF COUNTLESS STUDENTS AND THROUGH THEM THE LIFE OF THE COMMONWEALTH YOU HAVE SERVED THE UNIVERSITY NOTABLY AND WELL AS

ASSISTANT PHYSICAL DIRECTOR	1897 TO 1907
ASSISTANT IN OPHTHALMOLOGY AND OTOLOGY	1900 TO 1902
CLINICAL INSTRUCTOR IN OBSTETRICS	1902 TO 1906
CLINICAL PROFESSOR OF OBSTETRICS	1906 TO 1910
ASSOCIATE PROFESSOR OF OBSTETRICS AND GYNECOLOGY	1910 TO 1913
PROFESSOR OF OBSTETRICS AND GYNECOLOGY AND HEAD OF DEPARTMENT	1913 TO 1938

L. D. Coffman PRESIDENT M. Nimocks SECRETARY

GIVEN IN MINNEAPOLIS IN THE STATE OF MINNESOTA THE THIRTEENTH DAY OF JUNE IN THE YEAR OF OUR LORD ONE THOUSAND NINE HUNDRED AND THIRTY-EIGHT

He was honored by membership in the Sigma Xi and Alpha Omega Alpha honorary fraternities.

However, the high point of the esteem in which he was held locally was expressed on the occasion of the appreciation dinner given for him upon his retirement from the chair in 1938. In all, about 250 physicians, all his immediate colleagues, attended this testimonial of their love and respect. In addition to an oil portrait painted by Edward Brewer, which was presented to the University and which still hangs in his former department, there were many messages of commendation. Of these, the one from President Vincent, the Head of the Rockefeller Institute, is the most expressive and important. "I think of you with pleasure and gratitude. You were always calm, wise, humorous, and a steadying influence. You had ideals of research, teaching, and organization, to which you were steadfastly loyal. In times of stress and strain you kept your head and your temper. You will carry with you the assurance that you have played an important part in making the University of Minnesota Medical School one of the best in the country."

In 1934, Dr. Litzenberg and Dr. Olga Hansen, a member of the Department of Medicine of the Nicollet Clinic, astonished many of their friends by a quiet marriage. The amazement was soon replaced by pleasure, however, as the compatability and devotion of the two became apparent. Each followed his or her respective careers in medicine and when the inevitable confusion of names took place they facetiously stated, "It just as each was the recipient of the affection and regard of the other's friends and families.

The concern of Dr. Litzenberg for the young man was shared by Dr. Olga. Because of the dearth of rooming facilities in the region of the University, they opened their spacious and comfortable home, located on the margin of the campus, to a number of students each year. The depth of the meaning which attended the privilege of this hospitality is best expressed in the words of one of those who benefited from it: "In many respects he meant more to me than my own father; certainly he opened vistas which would have been denied me had I not been privileged to make my home with him for four precious years. He helped instrumentally to set the pattern for my own life, and as with me so it was with many others fortunate enough to have come under his guidance. There are many like myself who, as they undertake their responsibilities of parenthood or preceptorship, will seek to perpetuate that spirit of integrity, good humor, generosity, reverence, and grace, of which he was such a rare embodiment."

What more could be said by one who is not in the realm of science, but who has achieved success in a field far removed?

No biographical sketch of Dr. Litzenberg, however short or long, could be finished without a eulogy to the devotion given to him by Dr. Olga Hansen Litzenberg; a devotion which, when the inevitable physical infirmities overtook him, grew progressively in proportion as

the infirmities increased. She accompanied him to medical meetings in which he retained a lively interest until the very end, often at considerable distances. In the last years of the recent war when he carried a load of work far beyond the capacity of most men of his years, she accompanied him when he responded to night calls from the hospital. In the home she was constantly solicitous of his comforts and pleasures. In spite of her own heavy burden of professional work she found time to arrange and attend social functions which he also enjoyed until the time of his death. Only a few can completely and selflessly accept the privilege of service and devotion. Of these few Dr. Olga Hansen Litzenberg is one.

The record of the attainments and achievements of a man is only an appraisal of his abilities. The real appreciation of a man can come only through contacts with the multiple facets of his character. To know Dr. Litzenberg was to love him! To know him more intimately by working under his guidance was to cherish him still more. He was humble about his own accomplishments, but he was openly proud when some degree of success or any mark of distinction came to any in whose lives he had had some influence. Likewise, he was hurt and sorrowful when some one of these met with adversity.

It is not unusual that his Fellows held him affectionately in regard as the Chief and that he was devoted to them as "his boys." Such is the tradition of the teacher and student. But, it is unusual that he welcomed and applauded the inroads they made into his personal interests as they expanded as practitioners. He was always helpful. His interest in the potential accomplishments of those he met wherever he went and the stimulation and aid he gave to them established him as the Chief to many who had not trained directly under him. One of these living in a city far removed could write, "I first met the Chief in Washington in 1922. Since then he has been a professional father to me. His friends understood that I was one of "his boys." I can't express how much "My boy" has meant to me all over the United States."

The Head of the Department of Obstetrics and Gynecology in the Medical School of a well known University wrote the following. "He was always intelligent and kind and never too busy to help us in the young days of our clinic here." Many similar expressions of gratitude came from all parts of the country at the time of his death.

It was natural that Dr. Litzenberg, should be called "Litz" and sometimes "Litzie." In his daily life he was seldom addressed as Dr. Litzenberg. If one who knew him was in a distant place, and queries were made about various members of the local medical personages, almost invariably the first question asked was "How's Litz?" If others were asked about first, inevitably would come, "And how's Litzie?" He seemed to enjoy this abbreviation of his name and well he could because in it there was a connotation of affection and esteem. It could not violate the simple dignity that he was never without.

Courtesy was an inherent quality of the Chief, but during the period of the multiple demands of his most active life he could be brusque. If one were hurt by this paradox in his character, it did not last. With the next meeting complete assuagement came in his hearty and gracious salutation. On rare occasions he could be rude. He was repeatedly and openly boorish to a contemporary whose hidden principles he detested and which he had detected much earlier than had others. These incivilities were born of an outraged sense of propriety and were intolerable in his own straight and unpretentious way of thinking. He lived with a deep consciousness of the meaning of integrity.

Another of his inherent qualities was affability, but a violation of his deep sense of justice could produce strong indignation. At times he could forcefully voice his disapproval, but usually he contained himself in a significant silence. He could be highly tolerant of an error. On the other hand, a mistake, which to him implied omission, was inexcusable. Yet, whether in condemnation or in approbation, he was kindly.

He possessed a multiplicity of interests that could take him from the highest science of the lecture hall to an almost uninterrupted record of attendance at football games through many years. In his last years one would find him leaving the comfort of a warm home on a cold winter night to attend a lecture on some advanced scientific subject. On a Saturday when the short walk to the stadium had become a definite physical effort, he would brave the rigorous autumn weather to attend a football game. He challenged age to interfere with his participation.

He could discuss many subjects, some with brilliance and others always with competence. Yet he would never indulge in controversial topics. He appreciated a good story, but he was cold to "off color" yarns. He had wit, a faculty which made him a master of repartee in his earlier years. In his later years, as it was said of him in the Jennings C. Litzenberg Memorial Lecture, he had a chuckle which answered much.

The Chief is gone! To us who sat at his feet there can be no other Chief. He lighted a torch which we have striven to carry. He personified a great and rapid growth in obstetrics and gynecology. Through the medium of his own idealism he represented an ideal. He was Litzenberg—jocularly translated from German into English by himself—"A Light in the Mountains." *A bright light on a lofty height!*

CLAUDE J. EHRENBERG.

LEROY EDSON DOOLITTLE

Dr. LeRoy E. Doolittle, a well-known pediatrician of Duluth, died November 9, 1948, following a two weeks' illness.

Born in Genesco, Illinois, on March 8, 1883, Dr. Doolittle received his B.A. degree from the University of Minnesota in 1905 and his M.D. degree in 1909. In March, 1911, he married Bessie Kent.

After serving as a captain in the Medical Corps of the Army during World War I, he served as resident physician at the Children's Hospital in Boston from 1918 to 1920. He then located in Duluth and was medi-

cal superintendent of public schools for two years. His specialty was pediatrics and he was chief of pediatrics at St. Mary's Hospital in 1933.

Dr. Doolittle was a member of Phi Beta Pi medical fraternity, the Northwest Pediatric Society, the Central States Pediatric Society, the Academy of Pediatrics, the St. Louis County Medical Society and the Minnesota State and American Medical Associations. He was also a member of the Pilgrim Congregational Church, the Duluth Chamber of Commerce, and the Rotary Club.

Surviving are his widow; a daughter, Mrs. R. J. Hopkins of Duluth; three grandchildren, and a brother, Herbert E. Doolittle of Sioux Falls, South Dakota.

GEORGE BOODY

Dr. George Boody of Saint Paul passed away on November 11, 1948, at the age of ninety-three.

Born in Iowa, Dr. Boody practiced medicine in Iowa, Kansas, Alaska, Illinois, North Dakota and Texas before coming to Saint Paul thirty years ago.

Dr. Boody is survived by his wife; two sons, Hurd Boody of Saint Paul, and Dr. George Boody, Jr., of Dawson, Minnesota; a grandson; and a brother, Dr. Frank Boody of Eldora, Iowa.

FRANCIS E. GRISWOLD

Dr. Francis E. Griswold, a practicing physician at Hoffman, Minnesota, from 1899 until he retired from active practice two years ago, died November 1, 1948. He was seventy-four years old.

Dr. Griswold was born in Wisconsin Rapids, Wisconsin, March 21, 1874. He graduated from the University of Minnesota medical school in 1897 and took postgraduate work at the Post Graduate Polyclinic at Chicago in 1910.

Dr. Griswold is survived by his wife, Myra, two sons, Eugene F., of Minneapolis, and Myron W., of Crosby, Minnesota, and a daughter, Mrs. W. E. Clark of Minneapolis.

WILLIAM C. GULDE

Dr. William C. Gulde of St. Cloud died suddenly on October 28, 1948.

Dr. Gulde was born January 27, 1881, in Marshalltown, Iowa. He studied at Notre Dame University and graduated from Drake University medical school in 1907. He practiced at Bancroft, Iowa, before moving to St. Cloud.

He specialized in eye, ear, nose and throat diseases and was a member of the Stearns-Benton Medical Society, the Minnesota State and American Medical Associations. He is survived by his wife and a brother, Joseph F. Gulde, of St. Cloud.

JACOB ARTHUR JOHNSON

Dr. J. Arthur Johnson, of Saint Paul, died November 10, 1948, at the age of fifty-four.

Dr. Johnson was born December 20, 1893, in Saint Paul. He received his preliminary education at Minnesota College, and the degrees of B.S., M.B. and M.D. from the University of Minnesota in 1928. After graduation he interned at Ancker Hospital and served as resident at Mounds Park for six months. He was awarded the honorary degree of Alpha Omega Alpha as an undergraduate in medical school.

He was a member of the Gustavus Adolphus Lutheran Church, where he served as deacon for six years, and was in charge of compiling historical data for the anniversary book published on the fiftieth anniversary of the church. He was a member of the Ramsey County Medical Society, the Minnesota State and American Medical Associations. Unmarried, Dr. Johnson is survived by a sister, Mrs. Walfred G. Rohr of Saint Paul, and two nieces.

EARL F. JAMIESON

Dr. Earl F. Jamieson, of Brainerd, died suddenly of a heart attack on October 19, 1948, at the age of sixty-one.

Dr. Jamieson obtained his M.D. degree from the College of Physicians and Surgeons, Boston, in 1911, and specialized in eye, ear, nose and throat diseases.

He was a member of the Upper Mississippi Medical Society, the Minnesota State and American Medical Associations.

GARDNER SHAW REYNOLDS

Dr. Gardner S. Reynolds died in Saint Paul, October 16, 1948, at the age of fifty.

Dr. Reynolds graduated from the University of Minnesota Medical School in 1924 and practiced at Eau Claire, Wisconsin. He joined the staff of the Henry Ford Hospital, Detroit, in 1927. Later he became head of the x-ray department of St. Elizabeth's hospital, Danville, Illinois, until his resignation last April because of ill health.

Dr. Reynolds is survived by his wife, a son, Thomas, his mother, Mrs. Mae Reynolds, of Saint Paul, two sisters and a brother.

ALPHONSE E. WALCH

Dr. A. E. Walch of Minneapolis died November 14, 1948.

He was born in Rollingstone, Minnesota, February 19, 1907. He graduated from St. Mary's College, Winona, in 1929 and obtained his M.D. degree from St. Louis University Medical School in 1933. After interning at the St. Louis University Hospital, he took postgraduate training at the Minneapolis General Hospital from 1934 to 1936.

Dr. Walch was a member of the Hennepin County Medical Society, the Minnesota State and American Medical Associations, and was Clinical Assistant Professor of Medicine at the University of Minnesota medical school.

He is survived by his wife, Helen, a son and four daughters. His parents, Mr. and Mrs. Francis F. Walch of Rollingstone, and a brother, Ralph A. Walch of Le Sueur, also survive him.

Reports and Announcements

CHICAGO MEDICAL SOCIETY

The fifth annual Clinical Conference of the Chicago Medical Society will be held in Chicago at the Palmer House, March 1, 2, 3, and 4, 1949. The scientific program promises to be most outstanding with well-known speakers from all sections of the country discussing subjects which will be of interest to all physicians. Many scientific exhibits are being planned and the technical exhibits will be well displayed. Sufficient time will be given for viewing both of these exhibits.

One of the interesting features of the conference will be the luncheon round tables when questions will be answered by the speakers.

Physicians of other states and cities are cordially invited to attend this important medical meeting. Reservations should be made direct with the Palmer House.

UNIVERSITY COURSES IN OBSTETRICS AND OPHTHALMOLOGY

The University of Minnesota announces a three-day course in obstetrics for general physicians to be given at the Center for Continuation Study, January 6 through 8, 1949.

The University of Minnesota announces a one-week course in ophthalmology to be given at the Center for Continuation Study. The course is designed for ophthalmologists and will be presented during the week of January 24 through 29, 1949.

E. STARR JUDD LECTURE

The sixteenth E. Starr Judd Lecture will be given by Dr. Alton Ochsner, William Henderson Professor of Surgery at the Tulane University, New Orleans, Louisiana, Tuesday evening, January 18, 1949, at 8:15 in the Auditorium of the Museum of Natural History. Doctor Ochsner's subject is "The Treatment of Postphlebitic Sequelae by Vasodilatation and Other Measures."

The late E. Starr Judd, an alumnus of the Medical School of the University of Minnesota, established this annual lectureship in Surgery a few years before his death.

FREEBORN COUNTY SOCIETY

The Freeborn County Medical Society held a meeting in Albert Lea on November 4, and members heard a discussion of cancer by two University of Minnesota physicians. Dr. Arnold Kremen, of the cancer service of the University, spoke on cancer of the mouth and lips, while Dr. Robert A. Huseby, assistant professor of cancer biology, spoke on carcinoma of the breast.

During a business session, the Society selected Dr. F. W. Calhoun of Albert Lea as the outstanding general practitioner of the year from Freeborn County and voted to submit his name for the state nomination for the annual AMA award. Dr. Calhoun has practiced medicine for forty-one years.

SOUTHWESTERN MINNESOTA SOCIETY

At the annual meeting of the Southwestern Minnesota Medical Society, held in Worthington on November 1, Dr. John Lowman of Pipestone was elected president of the organization. Other officers named were Dr. Gerrit Beckering, Edgerton, president-elect; Dr. C. J. Pankratz, Mountain Lake, vice president; and Dr. B. O. Mork, Jr., Worthington, secretary-treasurer.

The principal speaker of the meeting was Dr. T. R. Fritsche, New Ulm, who presented an illustrated lecture on diseases of the eye.

The Society selected Dr. Ludwig L. Sogge, Windom, to be nominated for the honor of outstanding general practitioner in Minnesota.

WASHINGTON COUNTY SOCIETY

At a meeting of the Washington County Medical Society in Stillwater on November 9, the principal speaker for the evening was Dr. W. H. Thompson of Minneapolis. Dr. Thompson spoke on "Congenital Disease of the Hip" and illustrated his talk with numerous x-ray films.

PRACTICAL NURSE EXAMINATION

The Minnesota State Board of Examiners of Nurses will hold an examination for those applying for licenses to practice as Licensed Practical Nurses on Saturday, February 19, 1949, at 9:00 A.M. in the Mechanic Arts High School Auditorium, Saint Paul.

Completed applications for this examination accompanied by the fee of $7.50 must be in the office of the State Board of Examiners of Nurses, 222 Minnesota Building, Saint Paul 1, Minnesota, by January 19, 1949.

Fees must be paid by money order or bank draft; personal checks or cash will not be accepted.

Application blanks may be obtained from the board office.

CIVIL SERVICE POSITIONS FOR LABORATORY TECHNICIANS

Openings for medical laboratory technicians for positions for the most part in state institutions, are announced by the State Civil Service. Salaries range from $224 to $264 a month, and housing and board are obtainable at the institutions at a nominal cost.

Applications should be sent to the State Civil Service, Room 122, at the State Office Building, Saint Paul, Minnesota, before December 28, 1948. Examination will be held on January 8, 1949.

The inactivity following surgery or disease, and often encountered in the aged, makes constipation a likely occurrence. Dehydration, too, frequently is a significant contributing factor.

When the "smoothage" of Metamucil is employed in the management of constipation, normal evacuation is permitted without irritation or undue pressure on sutures and incisions. Thus straining is minimized.

Metamucil promotes smooth, normal evacuation by furnishing a non-irritating water-retaining colloidal residue in the large bowel.

Woman's Auxiliary

A PUBLIC RELATIONS PROGRAM FOR COUNTY AUXILIARIES

L. W. REMBER

Executive Assistant, American Medical Association

AS A NOUN, Webster says, "Auxiliary means a helper; an assistant." As an adjective, it means "in a helping manner." This is public relations in its finest sense; helping your doctor husbands to practice medicine in a *free* society; helping yourselves because you grow and gain great satisfaction from your achievements and contributions; helping your community get better medical care and medical services which brings it peace of mind and stamps out its fears.

Another definition which makes an excellent mental gymnastic for this morning's session is that of "Medical Public Relations."

Medical Public Relations is that function of the profession which evaluates public attitudes, identifies the policies and procedures of the profession with the public interests, and executes a program of action to earn public understanding and acceptance.

We can all agree, I believe, that this statement sounds mighty good and that the function of public relations deserves the wholehearted and continuous support of the medical profession and of the auxiliary. But this statement will only remain a group of beautiful words and noble phrases unless we translate it into action. Only action will earn public approval and public support for our goals.

It is highly commendable that your 26 county auxiliaries have already made great strides in effecting a program of action. But your being here today evidences that you are not the type of human being that is content to become mired in yesterday's achievements.

And so you have come together to expand your public relations activities and to refine your good-will-building techniques and methods.

In undertaking a program of public relations of any kind, it is necessary first to determine the nature and number of your publics. Otherwise you will not be in a strong position to serve them or to influence them.

An auxiliary to a county medical society, as I see it, has seven publics: two of them are in the area of *internal* relations and five of them are in the area of *external* relations.

Your *first* internal public is your own membership.

Your original purpose in being organized, as I understand it, was to promote companionship and sociability among wives of doctors. This is a noble public relations purpose. This association inclines you to feel kindly toward, and to speak well of, doctors' wives and of their husbands. This aids the profession.

Looking on the other side of the coin, when you speak ill of another doctor or of another doctor's wife, you injure the profession and every member of the profession, including your own husband. It is reassuring that the same charge cannot be made about doctors and doctors' wives in Minnesota, and in America generally, as was written about English doctors in explaining why they succumbed to socialized medicine.

Elizabeth Wilson is an outstanding American authority on compulsory health insurance. Recently she went to England to study first-hand why the British doctors were knocked out on July the fifth. In an appraisal letter to Dr. George F. Lull, our general manager and secretary, she said:

> It is very enlightening to see the different cliques among the doctors. I think that is the basic reason they failed—too much jealousy, too much individualism, too little co-operation. On the other hand, the government people, who are giving me quite a rush, work as one team. American doctors better take notice.

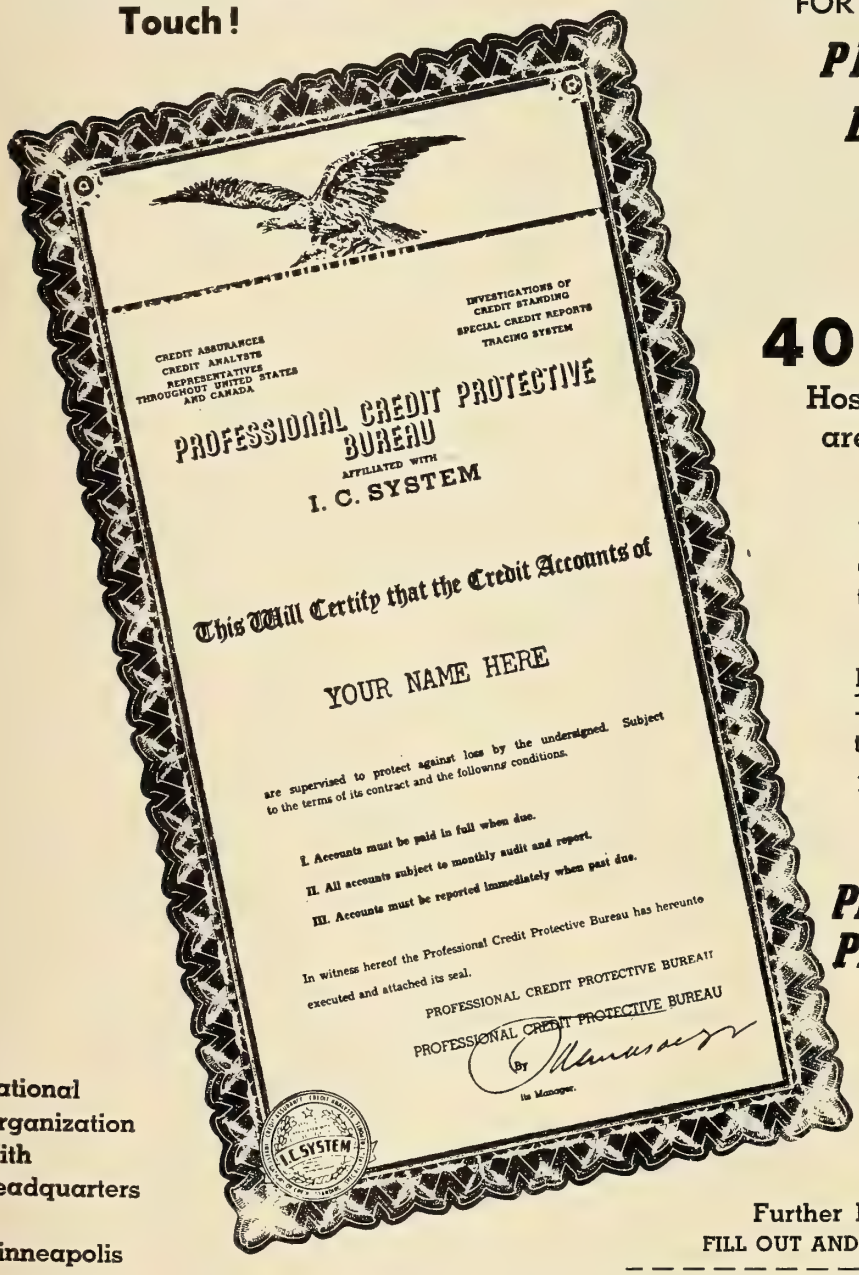
All of you fully appreciate, I'm sure, that one of the primary public relations responsibilities of auxiliary members is to cultivate and to maintain good will among the membership.

Another major membership responsibility in the area of internal relations is that of being informed about auxiliary affairs and aims; not only in reference to your own local unit, but also in reference to your state auxiliary and to your national auxiliary. Leaders particularly must keep informed. This, all of you are doing, I assume, by attending meetings regularly and by reading carefully through your local, state, and national bulletins, news letters, and special sections in the medical journal.

I might say here that this School of Instruction which you are holding here today is a splendid example of public relations indoctrination. In fact, I think it is unique, and the first I know of among state auxiliaries anywhere in the nation.

Public-relations-wise, it is important that this and all other valuable information which you acquire go beyond your own head and that it be funneled into the minds and motivations of your county auxiliary members. As Presidents, Secretaries and Committee Chairmen, you are the logical go-betweens. And if these ideas and this information do not pass on through you to them, they won't go anywhere. They'll just rust. And so might your county auxiliary!

Your *second* internal public consists of the county, state and national medical societies of which your husband is a member.



This is especially true because you have added to the original Auxiliary purpose of "promoting friendship

(Continued on Page 1370)

(Continued from Page 1368)

and mutual understanding among members." You have become aware of the expediency and desirability of encouraging happy situations and good will among all people. And so, your public relations chairman and your entire Auxiliary are seeking ways of "building a firmer relationship between the medical profession and the public."

Sound public relations naturally requires that Auxiliary members cannot say one thing and Medical Societies another in their public utterances and in their aims. There must be unity—of goal, of expression, of action. There is ample evidence that you people in Minnesota are fully aware of this. It is obvious from the program scheduled today that the State Medical Association and your State Auxiliary are working together most closely and co-operatively.

The fact that Dr. A. E. Cardle, president, Dr. E. M. Hammes, president-elect, Dr. Reuben F. Erickson, public policy committee chairman, and Dr. Paul C. Leck, Chairman on Rural Medical Service, are all appearing on this program shows that you are functioning as a team. This indicates that you appreciate that the public relations of the medical profession is the doctor's first responsibility, and that of necessity they must guide and approve of your public relations activities.

Commendable also is the closeness with which your State Auxiliary and Mr. Rosell worked in planning and developing this splendid program of today. I can say from past experience that I know that the Executive Secretary of the Minnesota State Medical Association has an unusual understanding of what is good public relations. The teaming up of his office with your School of Instruction Committee was bound to achieve a winning public relations touchdown.

At National Headquarters, Mrs. Kice and your national Board of Directors are co-operating most smoothly and effectively with President Dr. Roscoe Sensenich, President-elect Dr. Ernest Irons, the entire Board of Trustees chairmanned by Dr. Elmer Henderson, and General Manager and Secretary Dr. Lull. Dr. Edward L. Bortz, who served as President of the AMA during the past year, made the statement in Cleveland this January that "The Auxiliary is now beginning to assume its rightful role. It represents probably our most effective instrument in the field of public relations, which, unfortunately, has been the most neglected."

Your national auxiliary secretary, Mrs. Margaret Wolfe, has her offices in the AMA headquarters and is most helpful and co-operative. This same harmony and singleness of purpose operating at your state and national levels exists, I'm sure, between your county auxiliary and your county medical society.

These then are your two internal publics: your membership; and your county, state, and national medical societies.

We have already talked about the need for being informed about auxiliary affairs and aims. It is equally necessary that we keep informed and abreast of medical society activities and objectives. President Sensenich recently stated this well when he said: "As with all physicians, the first need for the members of the Auxiliary is to keep thoroughly informed of the issues which confront us."

The Journal of the American Medical Association, your own state journal, MINNESOTA MEDICINE, and

Dilaudid hydrochloride

(dihydromorphinone hydrochloride)

COUNCIL ACCEPTED

Powerful opiate analgesic - dose, 1/32 grain to 1/20 grain.

Potent cough sedative - dose, 1/128 grain to 1/64 grain.

Readily soluble, quick acting.

Side effects, such as nausea and constipation, seem less likely to occur.

An opiate, has addictive properties.

Dependable for relief of pain and cough, not administered for hypnosis.

● Dilaudid is subject to Federal narcotic regulations. Dilaudid, Trade Mark Bilhuber.

Bilhuber-Knoll Corp. Orange, N. J.

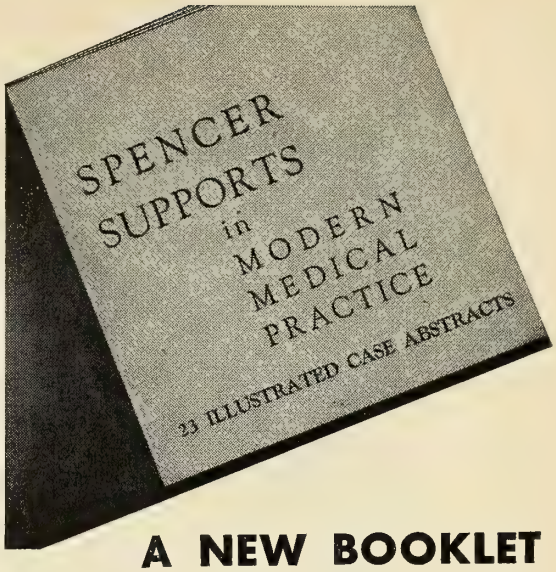
other medical periodicals and literature are excellent means of keeping authoritatively and currently informed.

This now brings us to the area of *external* relations, in which you, as an auxiliary to your county medical society, have five publics.

The *first* of these publics is the general public.

The medical profession has great need of the support and good will of the general public. It is the individual man and individual woman who make up the general public who will eventually by their cross on the ballot determine whether doctors are to practice under a voluntary or a compulsory system. The general public likewise through their legislative representatives will dictate what is done about animal experimentation, intrusion of third party between doctor and patient in the practice of medicine, status of medical cults, level of doctor income, amount of funds appropriated for research, education, and public health, and many other matters of vital importance to doctors and, therefore, wives of doctors.

The attitudes and opinions which members of the general public hold toward you as Mrs. Doctor will transfer itself for good or for harm to your doctor husbands. The admirable qualities of human nature such as kindness, tolerance, friendliness, and so forth will win friends. The objectionable qualities of personality such as high-hattedness, indifference, bigotry, and so forth will create enemies. In fact, whatever you say or do functions in tipping the scales one way or the other.



The number of people whom you will, or you can, contact individually and personally are limited, however. Consequently, it becomes necessary to seek some other means of reaching the masses, or the vast majority of people, who make up the general public.

This you can accomplish by employing the mass channels of communication and persuasion. These channels are your *second* external relations public.

They consist of your county newspapers, your county radio stations, your county magazines, house organs, and news letters, literature and other direct mail, your speakers' bureau, exhibits, films, and teachers, preachers, and other mass opinion leaders. On your program this afternoon, you have some outstanding representatives of some of these mass media of communication and persuasion, among them Dr. Thomas G. Hull of the A.M.A. who will talk on exhibits and films.

In your county auxiliary membership, you have undoubtedly found someone already who has an aptitude for writing, a sense of news, and who generally is awake to, and is capable of, taking advantage of public relations opportunities. No matter how talented this person is, however, there is little she can accomplish unless your county auxiliary is carrying on activities and achieving results in the public interest which are worthy of publicizing.

This brings you to the matter of program. Because you are doctors' wives and are serving as liaison between the medical profession and the public it is only logical, and certainly it is most effective, that your program operate in the field of health.

A NEW BOOKLET

Send coupon below for your copy

The first of its kind, this booklet is a summarization of practical therapeutic information on the use of supports in modern practice. Sources include thirty-eight articles and books from the current medical literature. Evidence of Spencer effectiveness is presented in a series of 23 abstracts of case histories, with photographic illustrations of each patient.

SUBJECTS: Protruded intervertebral disc, poliomyelitis, low-back pain, fatigue and lordotic posture, tumor of the spine, tuberculosis of the spine; hernia, fasciomyositis, postural syndrome, visceroptosis, colostomy; pendulous and engorged breasts, mastectomy, thoracoplasty; gravidity, normal and following spinal fusion, and other conditions where support is indicated.

For a dealer in Spencer Supports, look in telephone book under "Spencer corsetiere" or "Spencer Support Shop," or write direct to us.

SPENCER *INDIVIDUALLY DESIGNED* SUPPORTS
FOR ABDOMEN, BACK AND BREASTS

Your state membership is now eighth in the nation; and the number of county auxiliaries organized in your state exceeds that of 36 states. You have some splendid programs already functioning, and excellent new activities are on the drawing boards and will soon be ready to be launched.

Your regional health days are especially commendable. You are covering every section of your state with the health education schedule you have set up. I understand that the regional health day at Worthington last February brought in over 1,500 persons from the surrounding community. The featuring of both lay and professional health authorities on your program, and the inclusion of Governor Youngdahl, are excellent public relations, as is, of course, the event itself.

The laying of the foundation for the formation of local health councils for concrete community planning is another highly worthy public relations objective of health days. I am happy that I shall have the opportunity this afternoon to hear the procedures and techinques for planning these days discussed by Mr. William Griffiths.

You have conceived and carried out many other health education and health advancement programs which have contributed to the public welfare and which have served to identify and credit the medical profession with improving community health. These consist of aiding in nurse recruitment, giving leadership in campaigns on behalf of March of Dimes, Red Cross, Community Chest, Crippled Children, Christmas seals, cancer research, hospital building and equipment, social and mental hygiene, and preschool examinations.

You have informed yourselves about prepayment of medical and hospital bills, about socialized medicine, and other health problems and have spread and passed this knowledge on to the public or to special groups within the general public.

You have promoted health education by increasing the reading of *HYGEIA*.

You continue to serve as health chairmen of important groups organized primarily for other than health purposes and you wield your knowledge and your influence among their members in other ways and capacities.

In doing all of this you are functioning in the external relations area of *two other* key publics: organized health groups; and organized non-health groups.

The *fifth* vital public in the area of external relations is government.

Keep your eyes well peeled upon your city government, your county government, your state government, and your national government. Raise your voice, cast your ballot, organize others to strike down whatever public action or proposed legislation deteriorates health, and to support all that which advances health and the medical profession.

But make sure that the voice of medicine is speaking as one!

Remember all of your publics: your own membership, your medical societies, your community generally, your

Fifth CHICAGO MEDICAL SOCIETY ANNUAL CLINICAL CONFERENCE

March 1, 2, 3, 4, 1949

PALMER HOUSE • CHICAGO

A scientific program planned to bring information concerning newer developments in all fields of medicine and presented by a group of outstanding speakers.

A wide range of scientific exhibits which promise to be of special interest. Time given for viewing the well displayed technical exhibits. Luncheon round tables where your questions will be answered.

Make your reservations at the PALMER HOUSE

channels, other health groups, non-health groups, and your government. Learn and master the nature of each. Then serve them and motivate them so that the medical profession, and the public as well, will be benefited at all times.

Public relations requires stick-to-itiveness, just like raising kids or achieving suffrage. Women never say die and they seldom die young. This is all to your public relations' good.

Your husband doctors have the patients, spelled "p-a-t-i-e-n-t-s." And, if I understand at all you women leaders here today, you will have the patience, spelled "p-a-t-i-e-n-c-e," to achieve your public relations goals.

REGIONAL ADVISORS' TASKS OUTLINED

Hester Douglas Hammes

At the September meeting of the Woman's Auxiliary to the Minnesota State Medical Association, a round-table discussion was held by the regional advisors as part of the Workshop program.

The purpose of this discussion was to clarify and define, insofar as possible, the duties of the regional advisors. In the first place, the appointing of regional advisors was primarily intended to establish a closer contact between the state president and the county auxiliary presidents.

Ours is such a large state that it is almost impossible for a president from one section of Minnesota to know all about the background, difficulties, and problems of all the other parts of the state. To facilitate this closer tie-up between the state president and the outlying county auxiliaries, it was decided to divide Minnesota into nine districts, identical with the nine council districts of the State Medical Association. The doctors have found this particular division of the state satisfactory, and the Auxiliary thought it best to follow their example.

Now, with a regional advisor in each of the nine sections of Minnesota, a president can keep in touch with every individual auxiliary and so, because of the regional advisors, she can handle her office of State President with greater understanding and efficiency. Another important duty of the regional advisor is to work with the president-elect, who is also the organization chairman.

The advisor could be a very great help in getting preliminaries ready when a new auxiliary is to be organized in her district. She could strengthen doubtful auxiliaries and give help and advice to newly organized auxiliaries. The suggestions for this assistance should always come from the president and president-elect, who undoubtedly would be only too glad to profit from the greater knowledge at the disposal of the regional advisors.

As the State Medical Auxiliary has no executive secretary, I would suggest that each county auxiliary president, or her secretary, always send notices of the

next meeting to the regional advisor in time for her to plan ahead and arrange to attend the meeting, if possible.

It would be a splendid idea if the regional advisor could call a meeting of all the auxiliaries in her district once a year. It would give an opportunity to have an educational program. The State Medical Association office is always willing to send a speaker, if desired. This joint meeting would enable the women of different auxiliaries to get to know each other better and to exchange ideas, which would be of benefit to them all.

As can readily be seen, the position of regional advisor is no sinecure, but it is important. The future helpfulness of these advisors depends largely upon the tact they employ in being of assistance to the Association president and auxiliary presidents. I feel certain they will be of increasing usefulness to the organization and, in so doing, I wish them every success.

PRESIDENTS' ROUND TABLE BRINGS INFORMATION EXCHANGE

Mrs. John J. Ryan

A round table for county presidents was initiated at the Auxiliary Board meeting, held at the Radisson Hotel, September 26. Mrs. John J. Ryan, a past state president, served as moderator. Matters of mutual concern came up for discussion and, while nothing was settled, one could visualize the great benefit to be derived from future round-table meetings.

It was interesting to note that problems of the county societies are varied. The smaller counties have distance and weather to contend with, and the larger counties have other problems. An informal meeting, such as this, enables the members to become better acquainted, and constructive criticism was given as each one was called upon. This is truly a step in the right direction, and Mrs. Harold Wahlquist, state president, deserves much credit for her foresight in planning such meetings.

CLAY-BECKER GROUP REORGANIZES; PLANS YEAR

A reorganization meeting of the Clay-Becker Medical Society Auxiliary, attended by Mrs. Harold Wahlquist, state president, led to a new program of action for the coming year. The women have set these goals for themselves: sponsoring a nursing and teaching recruitment project, hiring a therapist to help patients at the Sand Beach Sanatorium, and holding a Health Day program. The doctors' wives will also plan for the sale, at Moorhead, Hawley, and Detroit Lakes, of articles made by the Sand Beach patients.

New officers for the Auxiliary, elected at the reorganization meeting, are: Mrs. C. W. Moberg, Detroit Lakes, president; Mrs. Oliver Moorhead, vice president; and Mrs. R. R. Hendrickson, Lake Park, secretary.

More Natural Vision . . . with MAY-O-LITE

Low Reflection Lens Coating is an inexpensive treatment that increases the efficiency and comfort of lenses.

Low Reflection Lens Coating reduces surface reflection 75 to 90%; helps harden the lens against surface scratches; renders the glasses less conspicuous, more natural-looking.

You, as a refractionist, can instantly realize what this means to wearers of glasses.

It diminishes eye-strain. It means more natural comfort and vision for your patients.

This new process, developed during the war as a means to improve image definition in military instruments, reduces surface reflection, yet increases transmission of light—and eliminates out-of-focus "ghost images."

Write for a descriptive pamphlet and a treated sample of glass today. Then explain Low Reflection Lens Coating to your patients. It is available through most manufacturing and dispensing opticians.

MOWER COUNTY GROUP BUSY WITH BANDAGES

Mrs. Paul Leck

The Auxiliary to the Mower County Medical society holds eight meetings a year, for which there is a planned program. There is always a supply of cancer dressings to keep hands busy, as well as minds.

The Auxiliary met October 25, at the home of Mrs. C. C. Allen, with Mrs. Harold F. Wahlquist, president of the State Auxiliary, as guest. She outlined the program of activities of the State Auxiliary and impressed upon the members the importance of sustained interest. The program of activities for the winter season will be considered at the next meeting.

NEW AUXILIARY IN McLEOD COUNTY

Mrs. A. M. Jensen

McLeod County doctors' wives recently organized the McLeod County Medical Auxiliary. Plans have been made to hold meetings the same evening that the doctors meet.

Officers for the coming year are: Mrs. A. M. Jensen, Brownton, president; Mrs. John Gridley, Glencoe, vice president; Mrs. L. L. Kallestad, Brownton, secretary-treasurer.

wives at a dinner on November 1. About fifty persons attended the dinner, after which motion pictures were shown.

* * *

In Norwood, early in October, Dr. Joseph Selmo moved into a newly decorated and better equipped office on the second floor of a local drug store. Dr. Selmo has practiced in Norwood for eight years.

* * *

The Wright County Medical Society met at the home of Dr. J. J. Catlin in Buffalo on October 26 to hear a talk by Dr. O. W. Scholpp, principal speaker of the evening.

* * *

Dr. Harold S. Diehl, dean of medical sciences at the University of Minnesota, has been named to an eleven-man advisory board for the United Mine Workers' welfare and retirement fund.

* * *

The Mayo Clinic was represented by five staff members at the meeting of the American College of Surgeons in Los Angeles during October. Participating in the meeting were Dr. J. H. Grindlay, Dr. J. B. Erich, Dr. G. B. New, Dr. J. T. Priestley and Dr. G. M. Roth.

* * *

A former Rochester resident, Dr. Donald G. Tollefson was named first vice president of the American College of Surgeons at its thirty-fourth clinical congress in Los Angeles on October 21.

Dr. O. J. Esser, formerly associated with the Hoidale-Workman Clinic in Tracy, opened offices for the practice of medicine in New Ulm on October 25. Dr. Esser specializes in diseases of the eyes, ears, nose and throat.

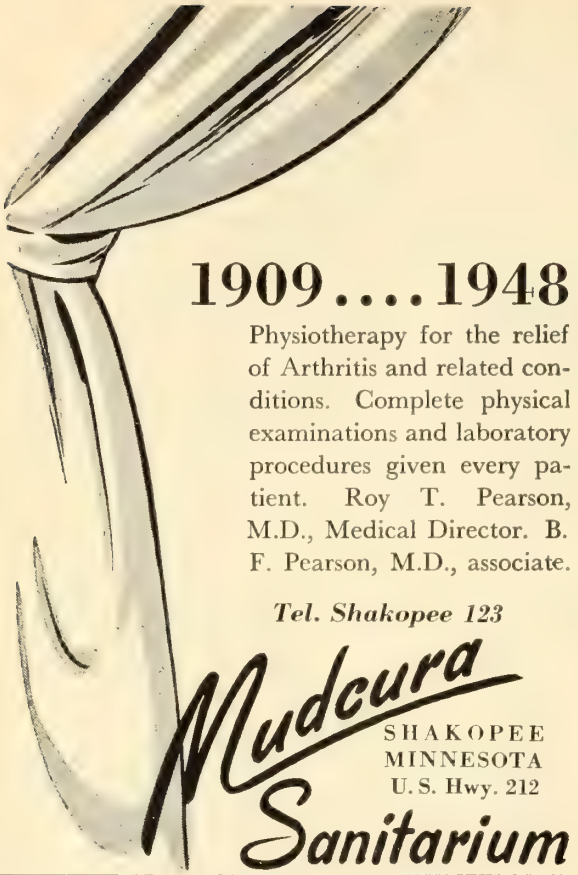
* * *

Among speakers at the South Central Minnesota Health Day, held in Mankato on October 13, was Dr. A. D. Mattson, St. James, who discussed "Better Medical and Hospital Care for Rural Communities."

* * *

Dr. W. L. Benedict, Rochester, was re-elected executive secretary-treasurer by the American Academy of Ophthalmology and Otolaryngology at its meeting in Chicago on October 15.

* * *



Among northern Minnesota physicians attending a meeting of the Minnesota Society of Internal Medicine in Rochester on October 18 was Dr. R. O. Sather of Crookston.

* * *

Dr. and Mrs. C. G. Uhley and Dr. and Mrs. O. K. Behr, of Crookston, spent the month of October in California, where they attended medical meetings and visited numerous cities of the state.

* * *

It was announced early in October that Dr. James R. Fox had moved his offices from 806 Physicians and Surgeons Building to 1325 Mount Curve Avenue, Minneapolis.

Dr. Donald H. Peterson, Saint Paul, has become associated with Dr. J. Richards Aurelius in the practice of radiology, with offices at 1355 Lowry Medical Arts Building, Saint Paul.

* * *

Two of the Minnesota physicians who attended a continuation course on gastroenterology at the University of Minnesota, October 21 through 23, were Dr. Ralph Wenzel, Albert Lea, and Dr. H. J. Nilson, North Mankato.

* * *

Dr. Oliver E. H. Larson, after his discharge from the Army, opened offices for medical practice in Zumbrota in October. A graduate of the University of Minnesota Medical School, Dr. Larson served his internship at the Good Samaritan Hospital in Portland, Oregon.

* * *

Included in the speakers at the first annual meeting of the Mille Lacs County Nursing Service, held in Milaca on October 4, were Dr. R. N. Barr, of the Minnesota Department of Health, and Dr. E. J. Simons, Little Falls, health officer of District No. 8.

* * *

Eighty-five physicians from Nicollet, Le Sueur and Blue Earth Counties, while attending a meeting of the Tri-County Medical Society in New Ulm on October 12, heard Dr. E. M. Hammes of Saint Paul speak on the diagnosis and treatment of head injuries.

* * *

Dr. Erling S. Platou, Dr. Allan J. Hill and Dr. Albert J. Schroeder have announced their association in the practice of pediatrics, with offices at 953 Medical Arts Building, Minneapolis, and at 3920 Sunnyside Avenue, Edina.

* * *

Dr. Margaret C. Anderson announces the opening of practice in anesthesiology. Dr. Anderson is a Diplomate of the American Board of Anesthesiology and may be reached through the Physicians Exchange in the Twin Cities or by telephone: Drexel 8932.

* * *

Dr. C. Anderson Aldrich, director of the Rochester Child Health Project, was honored by being given the Lasker Award, it was announced in October, for outstanding contributions to the education of physicians in the psychologic aspects of the practice of medicine.

* * *

In Glenwood, construction work on a new clinic building for Dr. Edward M. Elsey is expected to be complete by January 1. The one-story building provides space for a reception room, two offices, three consultation rooms, a laboratory, x-ray room, two storage rooms, a kitchen and a recreation room.

* * *

Dr. T. L. Davis, Jr., after completing a postgraduate course in ophthalmology and otolaryngology at the Chicago Eye and Ear Hospital, returned to Wadena about November 1 to resume practice with the other staff members of the Davis Clinic. Dr. Davis graduated from the University of Minnesota Medical school in 1946.

Dr. A. C. McKean, of the Fergus Falls State Hospital, left on October 28 for Hot Springs, Arkansas, where he has purchased a home and plans to spend the winter. At the time of his departure, it was not definitely known whether or not he intended to return to Fergus Falls in the spring.

* * *

Dr. and Mrs. A. C. Baker, Fergus Falls, combined a vacation trip in October with Dr. Baker's desire to attend the meeting of the American College of Surgeons in Los Angeles. After attending the meeting and visiting friends in southern California, they returned to Fergus Falls on October 26.

* * *

Dr. Edward Dyer Anderson, Minneapolis, was the principal speaker at the first 1948-49 meeting of the Southwest Parent-Teachers Association in Minneapolis on November 4. Dr. Anderson, a psychiatrist, discussed normal and abnormal emotional characteristics of adolescent children.

* * *

Speaking at a meeting of the Coleraine Women's Club on October 4, Dr. J. L. McLeod of Grand Rapids described his impressions and observations of eight South American countries which he visited while serving as a delegate to the Rotary International Convention in Brazil.

* * *

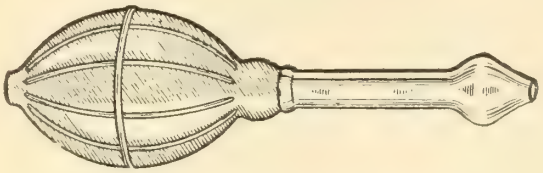
"Complications in Children's Disease and How to Avoid Them" was the title of a talk given by Dr. Robert Rosenthal, Saint Paul, at a meeting of Section 1 of the Child Psychology Study Circle in Saint Paul on October 4. Dr. Rosenthal is a clinical assistant professor of pediatrics at the University of Minnesota.

* * *

Dr. George N. Aagaard, University director of postgraduate medical education, conducted two three-day courses on Tuberculosis at the Center for Continuation Study in October for "family doctors" and for lay workers. Health education, case-finding surveys, and social and mental problems of the tuberculosis patient were discussed in the course for the lay workers.

* * *

"Cardiac catheterization" was described by Dr. Merrill C. Sosman, clinical professor of radiology at Harvard University, when he presented the annual Leo G. Rigler Lecture at the University of Minnesota on October 28. In his lecture he discussed the various ways in which radiological techniques can aid in the diagnosis of heart diseases.



* * *

Dr. Jack T. Murphy has become associated with Dr. Joseph M. Riga in the practice of internal medicine, with offices at 524 Lowry Medical Arts Building, Saint Paul. Dr. Murphy graduated from Northwestern Medical School in 1941 and served in the army at Oak Ridge. Recently he completed a residency in medicine at the Mayo Foundation.

that Dr. C. W. Parker of Denver, Colorado, would succeed Dr. S. Friefeld in Wadena. Dr. Friefeld plans to move to Duluth shortly before the first of the year to continue his radiology practice at a Duluth hospital. Dr. Parker received his medical degree and his training in radiology at the University of Colorado.

* * *

Approximately 800 persons attended a showing of motion pictures and a lecture by Dr. William P. Gjerde in Lake City on October 11. The color motion picture was taken in the Orient by Dr. Gjerde during his two and one-half years of service in the Army Air Forces. The program was sponsored by the Women's Club of Lake City.

* * *

Dr. Edward J. Engberg, superintendent of the Minnesota State School for the Feeble-Minded at Faribault, has been named president of the Rice County Public Health Association. A member of the board of directors of the state association, Dr. Engberg has been actively interested in tuberculosis control work for many years.

* * *

As a guest speaker at a regional conference of Minnesota welfare workers in Winona on October 11, Dr. C. Anderson Aldrich, Rochester, spoke on the subject, "Orderly and Lawful Behavior." Dr. Aldrich is director of the Rochester Child Health Project. Welfare organization representatives from thirteen counties attended the meeting.

* * *

The Children's Bureau, a unit of the Social Security Administration, has established a clearing house for research in child life to promote collaboration and interchange of information on current research in the various fields affecting child life. A bulletin on current research, which will be available to those interested, will be published in 1949.

* * *

Included in the Minnesota physicians who attended a three-day course in traumatic surgery and orthopedics at the University of Minnesota Center for Continuation Study, October 7 through 9, were Dr. F. G. Chermak, International Falls; Dr. L. Gordon Samuelson, Mankato; Dr. Theodore M. Hansen, Albert Lea; Dr. George W. Drexer, Blue Earth; Dr. N. W. Wagner, Graceville, and Dr. Troy G. Rollins, Elmore.

* * *

One of the speakers at a dinner meeting of the Citizens Committee of Sponsors of the Miller Hospital Building Fund in Saint Paul on November 17 was Dr. Charles W. Mayo, Rochester. The committee is sponsoring a campaign to raise funds for a 132-bed, six-story addition to Miller Hospital. At the dinner meeting the floor plans and the architect's conception of the new addition were shown publicly for the first time.

* * *

An honorary membership in the Minnesota Public Health Conference was awarded to Dr. Charles L. Scofield, pioneer physician in Benson, on October 8. Dr. Scofield, now eighty-three years of age and retired,

practiced medicine in Minnesota for sixty-two years. The award, given to him for distinguished service in the interests of public health, was announced at the annual meeting of the conference in Saint Paul.

* * *

A dinner sponsored by the Ellendale Commercial Club was given on October 6 to honor Dr. Edward Q. Ertel for his forty years of medical practice in the Ellendale community. A graduate of the University of Cincinnati, Dr. Ertel began practice in Ellendale immediately after completing his internship. He has served on the school board, the village council and the county draft board, and at one time was mayor of the community.

* * *

Private enterprise in medicine and hospitalization must be encouraged in Minnesota in order to advance the health of residents of the state, Governor Luther Youngdahl said in a radio address on October 12. "We must guard against the stifling of progress which might result from resort to socialization of medicine," the governor stated. He was introduced on the program by Dr. A. E. Cardle, president of the Minnesota State Medical Association.

* * *

One of the speakers at a seminar on industrial medicine and surgery, held in Minneapolis during the middle of October, was Dr. Hewitt B. Hannah, Minneapolis, who told the 100 assembled industrial physicians to pay attention to the worries as well as the injuries of their accident patients. "Nearly every traumatic injury patient develops deep anxieties about the results of his injuries and what will happen to his family," Dr. Hannah said. These anxieties, he added, can have a serious effect on the treatment given the patient.

* * *

Members of the Minnesota Society of Internal Medicine, meeting in Rochester on October 18, elected Dr. John A. Lepak, Saint Paul, president of the organization. Other officers named were Dr. F. H. K. Schaaf, Minneapolis, vice president, and Dr. A. E. Brown, Rochester, secretary-treasurer. About eighty members of the society attended the biannual meeting, at which fourteen talks on internal medicine were presented. In the evening Dr. Oliver N. Beahrs completely bewildered members and guests with her legerdemain exhibition.

* * *

Announcement was made on October 13 that Dr. Kenneth J. Johnson, formerly of Saint Paul, had joined the staff of the Bemidji Clinic. Dr. Johnson, a graduate of the University of Minnesota Medical School and holder of a master of science degree in bacteriology, served his internship at Wayne County General Hospital, Michigan. After a period of service in the armed forces, he took postgraduate work in internal medicine at the University of Minnesota. During the past summer he completed a medical residency at Wayne County General Hospital.

The National Society for Crippled Children and Adults, which includes the various state units, and devotes itself to the education, rehabilitation and employment of all handicapped persons, is supported by the annual sale of Easter Seals. The society announces an annual grant of $5,000 by the college sorority, Alpha Gamma Delta, for the training of a limited number of vocational workers and job-placement technicians specializing in the employment problems of persons disabled by cerebral palsy.

* * *

Dr. Edward J. Richardson has opened offices with Dr. F. E. B. Foley at 228 Lowry Medical Arts Building, Saint Paul, for the practice of urology. A graduate of Johns Hopkins medical school, 1943, Dr. Richardson interned in urology for nine months at Johns Hopkins Hospital, practiced at Pierre, South Dakota, and was assistant resident in urology at the Ancker and Miller Hospitals, Saint Paul, for a few months before serving ninteen months in the Army. From July 1, 1947, to July 1, 1948, he was resident in urology at the Ancker Hospital.

* * *

Dr. N. L. Werner and Dr. S. H. Anderson, both of Red Wing, became associated in practice on November 1, when it was announced that the two of them would jointly conduct the Red Wing Clinic.

Dr. Werner previously practiced in Red Wing from 1908 until 1943, at which time he became resident physician at the state hospital in Hastings. Dr. Anderson has practiced in Red Wing since 1922, much of the time with Dr. A. E. Johnson in the Red Wing Clinic. After the retirement of Dr. Johnson several months ago, Dr. Anderson conducted the clinic alone.

* * *

A report issued during the first week of November from the Cancer Detection Center at the University of Minnesota showed that more than half of the 957 persons examined during the first seven months of the Center's operation were found to require medical attention.

Among the abnormal conditions discovered in 527 persons were the following: 15 definite cases of cancer, 235 precancerous lesions, 131 benign tumors, 49 suspicious tumors, and 270 nontumorous but non-normal conditions.

The 430 persons found to be apparently in good health were advised to return to the Center for re-examination every six months. Of the 957 persons examined, 478 were women and 479 men, all aged forty-five or over.

* * *

Among Minnesota physicians who attended a three-day course in methods of diagnosis and treatment of tuberculosis and other diseases of the chest at the University of Minnesota Center for Continuation Study, October 18 through 20, were Dr. L. Kenneth Onsgard, Houston; Dr. G. A. Miners, Bemidji; Dr. Ralph L. Estrem and Dr. W. O. B. Nelson, Fergus Falls; Dr. F. M. McCarten, Stillwater; Dr. E. C. Burseth, Forest Lake; Dr. Stella L. Wilkinson, Faribault; Dr. Russel R. Hendrickson, Lake Park; Dr. Sidney A. Whitson, Albert Lea, and Dr. B. J. Cronwell and Dr. F. H. Rosenthal, Austin.

* * *

The Rehabilitation Center has been established in Saint Paul, sponsored by the Junior League of Saint Paul, the Minnesota Society for Crippled Children and Adults, with space supplied by the Wilder Charities of Saint Paul at the Wilder Dispensary. Mrs. B. R. Rutherford is in charge. Physicial therapy in the form of heat radiation, massage and hydrotherapy, occupational therapy and speech training are furnished on a part pay and free basis. The Center is a nonprofit organization, and its policies are determined by a medical advisory board composed of seven members of the Ramsey County Medical Society.

* * *

Rochester, though packed with medical personnel, urgently needs more physicians—but the ones needed are general practitioners.

So stated Dr. William F. Braasch, retired Rochester physician, when he came out of retirement in late October to lead a campaign for the construction of a community hospital. Other than the hospitals associated with the Mayo Clinic whose facilities are utilized almost com-

HOMEWOOD HOSPITAL is one of the Northwest's outstanding hospitals for the treatment of Nervous Disorders—equipped with all the essentials for rendering high-grade service to patient and physician.

pletely by the clinic, there isn't a hospital within forty miles of Rochester. Though world-known as a medical center, Rochester is the only community of its size in the United States without a public hospital, Dr. Braasch said.

Partly because of the lack of hospital facilities, there are only three or four general practitioners in all of Olmsted County. "The scarcity of doctors of this type is a detriment to the health of the people of this community," Dr. Braasch stated.

* * *

Two Saint Paul surgeons and three Minneapolis surgeons were admitted to membership in the International College of Surgeons, when the United States chapter of the organization held its thirteenth annual assembly and convocation in St. Louis, Missouri, November 15 through 19.

New members from Saint Paul are Dr. Robert J. Richardson and Dr. Edward V. Davis, while those from Minneapolis are Dr. Earl H. Dunlap, Dr. Alvin J. Kistler and Dr. Lloyd A. Whitesell.

Named as an associate fellow of the group was Dr. Howard A. Vogel of New Ulm. Dr. E. K. Ingebrigtson of Moorhead was elected as an affiliate of the organization.

* * *

Collecting books written by persons suffering from mental or physical illness is the rather unusual semi-hobby of Dr. Walter C. Alvarez of Rochester.

His collection includes books by psychotics, neurasthenics, alcoholics, "dope" addicts, hunchbacks, paralytics, spastics and others. Some of the books were written while the authors' illnesses were just beginning, others after recovery had occurred. Many of the volumes are by well-known journalists and authors who were "going insane" or were addicted to morphine or alcohol.

Dr. Alvarez began his collection in 1907 when he first obtained Charles Beers' "A Mind That Found Itself." Since then, the unusual library has grown steadily, encompassing, for example, a story written by De Maupassant as his mental illness began. A recent addition to the collection is the fairly new book, "The Snake Pit."

"Through reading the books in my collection," Dr. Alvarez said recently, "I have learned to understand better the ways people in these unfortunate situations think, and what they like and do not like in their handling by physicians. Their writings are often amazingly frank."

At the annual staff meeting at Northwestern Hospital, Minneapolis, in September, Dr. R. S. Ylvisaker was elected president of the attending medical staff. He succeeds Dr. J. C. Miller in the office. Named as vice president was Dr. Edwin G. Benjamin, while Dr. Albert T. Hays was elected secretary-treasurer.

Named as new members of the executive committee were Dr. Lawrence Larson, Dr. Chauncey A. McKinlay, Dr. Samuel B. Solhaug, Dr. Kenneth J. St.Cyr, Dr. Cyrus O. Hansen and Dr. Stanley Lofsness.

* * *

BLUE SHIELD NEWS

Applications received for Blue Shield to October 30, 1948	100,309
Blue Shield cases paid from October 1 to October 30, 1948	726
Total, 1948	2,573
Amount paid on Blue Shield cases from October 1 to October 30, 1948	$ 26,706.19
Total, 1948	95,674.80

Blue Shield, the voluntary prepaid plan for medical and surgical care, can be an influential factor in counteracting suggested compulsory health insurance. In Minnesota, Blue Shield is comparatively new, but as the above figures show it already is functioning to the benefit of a large number of subscribers. As it continues to expand it will publicize itself. In the meantime Blue Shield needs to be brought to the attention of all residents of this state, and such contact is perpetually under way through the Blue Shield representatives in the field. However, it is believed that the doctors of Minnesota could do a tremendous service to Minnesota Medical Service, Inc., by bringing the advantages of Blue Shield to each patient's attention and emphasizing to the patient that he personally approves the plan. The "family doctor's" sanction of Blue Shield is often the determining factor in proving its worth to his patient.

Blue Shield provides benefits for the following services rendered by licensed doctors of medicine: for surgery and obstetrical deliveries in the hospital, the patient's home, and the doctor's office; for medical care rendered to a hospitalized bed-patient; for x-rays taken at the direction of a doctor of medicne if they are related to the above services; for the services of an anesthesiologist. In each instance the allowance is determined by the actual service rendered and payment made in accordance with the Blue Shield Schedule of Payments.

The advantages of Blue Shield are twofold—not only does it provide for the services of a doctor of medicine during illness, thereby carrying for the Blue Shield contract holder the burden of financial expense, but also it assures the physician of at least partial payment from the Blue Shield office for his services. The plan does not attempt to cover routine or miscellaneous minor services, but rather attempts to provide for serious illness as well as all surgery—in other words, major expenditures.

Through the co-operation of the Red River Valley Medical Society, an extensive campaign publicizing the Blue Shield plan has been under way during October and November during which time the doctor's offices, the hospitals, the farm bureau headquarters, the nurses, druggists, schools and newspapers together with the radio stations in the area have assisted in bringing the plan to the attention of residents of that area. In addition, some time was spent by Blue Shield office personnel in contacting the medical personnel of the doctor's offices and clinic in the area relative to the processing of Blue Shield claims. It is anticipated that similar programs may be carried out in other sections of the state.

November 15, 1948, marks the anniversary of the first Blue Shield contract to become effective in Minnesota. The co-operation of the Blue Shield participating doctors of medicine during this first year of operation has done much to assure its success. However, there remains the tremendous educational job to be done for Minnesota Medical Service Inc.—the doctor's assistance in this task will be of inestimable value. Blue Shield as a voluntary plan appeals to the American public, something which is desired is much more acceptable than something to which we must subscribe—Blue Shield services are ample and the contract cost nominal. It is the doctor's plan for the benefit of his patient. A smoothly and expeditiously functioning voluntary, nonprofit medical, surgical, and obstetrical plan is our most adequate defense against any proposed national plan for compulsory health insurance.

BOOK REVIEWS

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

PATHOLOGY. Edited by W. A. D. Anderson, M.A., M.D., F.A.C.P. Professor of Pathology and Bacteriology, Marquette University School of Medicine, Milwaukee, Wisconsin. 1453 pages. Illus. Price $15.00, cloth. St. Louis: C. V. Mosby Co., 1948.

AN INTRODUCTION TO GASTRO-ENTEROLOGY. Fourth Edition. Walter C. Alvarez, M.D. Professor of Medicine, University of Minnesota, the Mayo Foundation, a Senior Consultant in the Division of Medicine, The Mayo Clinic. 903 pages. Illus. Price $12.50, cloth. New York: Paul B. Hoeber, Inc., 1948.

THE CASE AGAINST SOCIALIZED MEDICINE. A constructive analysis of the attempt to collectivize American medicine. Lawrence Sullivan. 53 pages. Price $1.50, cloth. Washington, D. C.: Statesman Press, 1948.

HEART. A Physiologic and Clinical Study of Cardio-Vascular Diseases. Aldo A. Luisada, M.D. Instructor in Physiology and Pharmacology, Tufts College Medical School Lecturer in Medicine; Lecturer, Postgraduate Division, Tufts College Medical School; Associate in Medicine, Beth Israel Hospital, Boston, Mass.; Former Professor of Medicine, Ferrara, Italy. 653 pages. Illustrated. Baltimore: Williams & Wilkins Company. Price, $10.00.

This textbook represents a great deal of work on the part of its author. Because of our increased knowledge of heart disease and the great amount of literature that has been published in the past ten years, it is difficult to correlate the valuable material and to separate it from the less valuable. The author attempts to do that in his book and has accomplished something in doing so. However, the book is incomplete when one considers it as a text book on heart disease in that there is little space given to the discussion of treatment, although I say this with the knowledge that there is little to be said about treatment in many cases. But treatment is much more appreciated if the philosophical background is presented.

It is an excellent treatise on the anatomy and physiology of heart disease. I would recommend the book for library use only.

JOSEPH M. RYAN, M.D.

OFFICE IMMUNOLOGY; INCLUDING ALLERGY: A GUIDE FOR THE PRACTITIONER. Edited by Marion B. Sulzberger, M.D., Professor of Clinical Dermatology and Syphilology, and Director, New York Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, and Rudolf L. Baer, M.D., Instructor in Dermatology and Syphilology, New York Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital. 420 pages. Illus. (General Practice Manuals). Chicago: Year Book Publishers, Inc., 1947. Price $6.50.

It is no small treat to review the varied authors' compilation, "Office Immunology." Contained therein is a tremendous amount of concise and useful information dealing, for the most part, adequately with a wide range of immuno-biological procedures. Obviously, in presenting so vast and complex a subject, streamlining has been necessary, but this has not denied the reader the essential details in implementing a given technique.

Allergy, in its many important clinical phases, is lucidly and usefully presented. A substantial segment of this book is devoted to phylactic and prophylactic anti-bacterial and anti-viral measures. In many instances, where specific information or individual experiences have allowed, the authors have attempted to assess the value and/or pitfalls of the subject being considered. Neither has there been forgotten the ever-present difficulty of locating precise sources of immunological material, and whenever possible such sources are indicated. Whether your chosen field is basic or clinical medicine, this book is a "must."

To my knowledge, nowhere in a single handy volume is there to be found such authoritative, selectively condensed information on immuno-biological phenomena as applied to medicine.

S. MACKOFF, M.D.

HANDBOOK ON FRACTURES. Duncan Eve, Jr., M.D., F.A.C.S., Surgeon-in-Chief, Nashville, Chattanooga and St. Louis Railroad; District Surgeon, Louisville and Nashville Railroad; Associate Professor of Surgery, Vanderbilt University School of Medicine; Member of the Southern Surgical Society; Member of The American Association for the Surgery of Trauma; Chairman of the Committee on Fractures of the Medical and Surgical Section of the American Railroad Association; Member of the Committee on Fractures of the American College of Surgeons; Attending Surgeon, St. Thomas Hospital, Nashville, Tennessee, in collaboration with Trimble Sharber, A.B., M.D., Attending Surgeon, St. Thomas Hospital, Nashville, Tennessee. 263 pages. Illustrated. St. Louis: C. V. Mosby Co., 1947. Price $5.00.

This concise and authoritative résumé of fracture treatment will be a welcome handy reference for students and general practitioners. The material is well organized for handy reference.

The illustrations are adequate and clear.

S. W. SHIMONEK, M.D.

FUNDAMENTALS OF CLINICAL NEUROLOGY. H. Houston Merritt, M.D., Professor of Clinical Neurology, College of Physicians and Surgeons, Columbia University; Chief of Division of Neuropsychiatry, The Montefiore Hospital; Fred A. Mettler, M.D., Ph.D., Associate Professor of Anatomy, College of Physicians and Surgeons, Columbia University; and Tracy Jackson Putnam, M.D., Professor of Neurology and Neurological Surgery, College of Physicians and Surgeons, Columbia University. 289 pages. Illustrated. Philadelphia: The Blakiston Company, 1947. Price, $6.00.

This is an interesting, well written book of less than 300 pages that combines a brief review of neuro-anatomy and physiology with the clinical aspects of neurology. The first portion dealing with examination of the nervous system covers particularly well the cranial nerves. One might wish for more attention to the testing of peripheral nerves, and especially the inclusion of some diagrams of nerve injury.

The remainder of the book deals with anatomic diagnosis. It does this by considering the nervous system segmentally: peripheral nerves, spinal cord, brain stem, et cetera. In each subdivision after covering the anatomy, blood supply, and physiology, there is a brief consideration of diseases and clinical syndromes. In a book this brief there is little space given to details of therapy, but the chief therapeutic agents are mentioned. A valuable chapter is the one on cerebro-spinal fluid giving an extensive listing of cerebro-spinal fluid changes in various diseases.

—D.M.C.

Glenwood Hills Hospitals

Teaching Staff

signalizes 10 years of progress in instruction in psychiatric nursing

The demand for Glenwood Hills Hospital's nurses is an endorsement of their excellent training in the essentials—modern methods and modern patient care—achieved in a one-year, practicality-packed, time-conserving course that gives everything a high school graduate needs to be useful to doctor, patient, hospital and community; and nothing she does not need.

TEACHING STAFF

NATHANIEL J. BERKWITZ, M.D., Ph.D.
Assistant Clinical Professor
Neurology and Psychiatry
University of Minnesota

SHOULD VITAMIN D BE GIVEN ONLY TO INFANTS?

VITAMIN D has been so successful in preventing rickets during infancy that there has been little emphasis on continuing its use after the second year.

But now a careful histologic study has been made which reveals a startlingly high incidence of rickets in children 2 to 14 years old. Follis, Jackson, Eliot, and Park* report that postmortem examination of 230 children of this age group showed the total prevalence of rickets to be 46.5%.

Rachitic changes were present as late as the fourteenth year, and the incidence was higher among children dying from acute disease than in those dying of chronic disease.

The authors conclude, "We doubt if slight degrees of rickets, such as we found in many of our children, interfere with health and development, but our studies as a whole afford reason to prolong administration of vitamin D to the age limit of our study, the fourteenth year, and especially indicate the necessity to suspect and to take the necessary measures to guard against rickets in sick children."

*R. H. Follis, D. Jackson, M. M. Eliot, and E. A. Park: Prevalence of rickets in children between two and fourteen years of age, Am. J. Dis. Child. 66:1-11, July 1943.

MEAD'S Oleum Percomorphum With Other Fish-Liver Oils and Viosterol is a potent source of vitamins A and D, which is well taken by older children because it can be given in small dosage or capsule form. This ease of administration favors continued year-round use, including periods of illness.
MEAD'S Oleum Percomorphum furnishes 60,000 vitamin A units and 8,500 vitamin D units per gram. Supplied in 10- and 50-c.c. bottles and bottles of 50 and 250 capsules. Ethically marketed.
